The book consists of 11 chapters, the last being an epilogue on the archaic attitude of the general public towards alcoholism. The popular attitude towards the chronic alcoholic has been to condemn and to make a moral issue. This popular conception, with its indignant attitude and vindictive outlook, stands in paradoxical relationship to the opinions of poets and philosophers who have sung of the joys of drinking down through the ages. These two paradoxical attitudes are broadly but forms of individual rationalization and probably bear a relation to the popular concepts respecting individual responsibilities involving choice of behavior. The author implies, however, that this popular concept must be replaced with a more scientific one of natural phenomena being an endless chain of cause and effect.

It is not possible to understand the nature and causes of wickedness, of the bad and the sordid, or the mean and the vile, or the abandonment of all those things by which men ordinarily live, if the approach is in the direction of intolerance and condemnation for alcoholism. The problem drinker cannot be understood, satisfactorily treated, or his condition ameliorated or prevented through an emotional outlook that is influenced by a spirit of vindictiveness or maudlin sympathy. With the above premise in mind the theme of this volume is perhaps expressed in the author's own words, thus, "Modern therapy of alcoholism takes its stand on practical grounds. Its effort to change conduct, unlike the miracle methods of old, are based on the hypothesis, confirmed by both research and common sense, that the behavior of an individual is the interaction of himself and his circumstances. If we recognize alcoholism as a symptom of some difficulty of the whole man and deal with it realistically we rob it of its terrors and offer freedom and happiness to countless harassed problem drinkers."

The volume is vouched for in a signed foreword by Dr. Arthur Ruggles, Superintendent of Butler Hospital, Providence, Rhode Island, who comments that the methods of approach to the problem drinker as outlined by the author are superior in many respects to those previously prevailing.

The author expresses the hope that the book may be of value to the family physician, the clergyman, the welfare worker and the public administrator, and all who come in contact with the drink problem. It is obvious that many family physicians are consulted from time to time concerning the best methods of approaching the problem drinker who is detrimental to himself and those nearest and dearest to him. In the use of this little book serious consideration might be given to the possibility of its being placed on the family physician's reading list for prescription to the problem drinker and those who come in contact with him, since the book affords many passages to stimulate reflection for the problem drinker to better know himself.

In analyzing the theme of this publication one somehow automatically turns to the writings of that great humanitarian, Charles Dickens, who said, "Who turns his back upon the fallen and disfigured of his kind, abandons them as vile, and does not trace and track with pitying eyes the unfenced precipice by which they fell from good, does wrong to Heaven and man, to time and to eternity."

W L T

The Diagnosis and Treatment of Diseases of the Stomach and Intestines By WILLIAM FITCH CHENEY, B.L., M.D. 378 pages, 15.5 × 24 cm Oxford University Press, New York 1936 Price, \$5.50

This volume is one of the Oxford series of "Monographs on Diagnosis and Treatment" The author has attempted to present the subject of the diseases and disturbances of the gastrointestinal tract in sufficient detail for practical use and still to avoid lengthy theoretical discussion Certain subjects of interest to the specialist are necessarily omitted The treatise is based on the author's own experience and contains very few references to the literature but the occasional authority to whom attention is called shows clearly that the volume is up to date Moreover, the discussions of gastroscopy and gastrophotography give the same impression

The book is divided into two parts, one devoted to "Diseases of the Stomach," and the other to "Diseases of the Intestines" Both parts are developed according to the same plan so that the second half of the volume, with certain exceptions, is a counterpart of the first Throughout the volume the discussions are clear and concise Case reports are presented briefly and so effectively that they may be said to illustrate the text

Although the volume contains all the essential data necessary in the modern study and treatment of gastrointestinal disease it nevertheless is not a satisfactory reference book for the specialist It probably was not meant to be Furthermore, although it avoids controversy the writer's conviction that gastropnoxis is associated many times with disturbances of digestion and that correcting the former removes the latter may be responsible for a good deal of debate

By succinctly presenting the diseases under discussion and bringing them up to date with regard to diagnosis and treatment and by stressing the care that must be taken in localizing a pathologic change in the proper organ the writer has given us a splendid part of an excellent system of books

S M

Treatment in Psychiatry By OSKAR DIETHELM, M.D. 476 pages, 16 × 24 cm Macmillan Company, New York, N.Y. 1936 Price, \$4.00

There are so remarkably few volumes devoted to the treatment of the mental disorders that such a one is very welcome It is carefully and thoughtfully written It is fundamentally sound

It begins with a study of personality, followed by general principles of treatment, then proceeds to an exposition of suggestive and hypnotic procedures, psychoanalytic procedure, and the special psychotherapeutic variations of Adler, Jung, Trigant-Burrow, Rank and Stekel, Du Bois, and Kronfeld, as well as the indirect methods represented by association experiments and Rorschach's Tests

Dr Diethelm then presents his own general views (and those of Dr Adolph Meyer's followers) in a chapter called Distributive Analysis and Synthesis

The rest of the book consists of detailed examination of what he feels to be the primary considerations to be dealt with in each type of disorder He tells how he handles these problems as they arise and illustrates with pertinent and well chosen case history briefs

The whole presentation seems to us distinctly on the dogmatic side In a work of this kind this is not a bad fault since it is designed to be used by physicians in general, who may not be too familiar with the diversity of views held by professional psychiatrists, but who are looking for concrete treatment programs to follow

We feel it does not adequately stress the enormous therapeutic value of the simple rapport or physician-patient fellow-feeling relationship which leads to many recoveries regardless of any technics It lays much too much stress on the use

of drugs, particularly sedatives. Here they would seem to hold a prominent if not preeminent place in every treatment program. They do have their usefulness—in selected cases—but we would have preferred to see the author sound a note of caution in their use.

We have always been curious as to the reasons why hypnosis receives as much attention as it always seems to, in view of the fact it is now so little used.

This book will naturally be of much more use to the psychiatrist than to physicians outside this especial field, but is probably the best treatment text in English which has so far appeared.

H M M

Clinical Allergy By LOUIS TUFT, M D 711 pages, 24 × 15½ cm W B Saunders Co, Philadelphia and London 1937 Price, \$8 00

This book is an eminently satisfactory manual of practical allergy. It should be useful to the general practitioner and student and, in addition, should prove of value as a manual of practical procedures for allergists and for technicians connected with allergy clinics.

Dr Tuft, while giving the background of the subject and presenting the important points of its development together with the various views held, on different phases of the subject, is sufficiently dogmatic to make the text workable as a practical guide.

The arrangement of the book is quite satisfactory. He first considers the general principles involved, explaining the mechanism of anaphylaxis and allergy and giving the general principles of diagnostic and therapeutic methods. He next considers allergic conditions from an etiological standpoint. Under this section he discusses serum, drug, food, pollen, bacterial and physical allergy. The third section considers allergy from the standpoint of its clinical manifestations, taking up asthma, allergic rhinitis, gastrointestinal allergy and migraine.

His fourth section, which is called Allergic Dermatoses and Allergy in Relation to the Specialties should be most valuable to men in other fields, especially those interested in nose and throat diseases.

Not the least important portion of the book is the appendix. Here, Dr Tuft covers the laboratory methods in anaphylaxis and in allergy, describing under the latter the passive transfer method of Prausnitz-Kustner, the preparation of liquid and dry allergenic extracts and the preparation of pollens for microscopic examination. He also gives practical, detailed directions for asthma and hay-fever patients. A very valuable feature is the list of the possible allergens in household materials and in foods, together with a list of allergens and their sources. There are allergic diets and recipes which should be most helpful and his bibliography should prove very valuable to anyone interested in the subject.

The book contains a moderate sized but valuable group of pictures. The author has avoided the inclusion of useless photographs which so frequently appear in texts of this sort.

A novel and valuable feature is the use of case vignettes to demonstrate and clarify clinical points under discussion.

The excellent section on pollen allergy leans heavily upon the work of Thommens (Coca, Walzer and Thommens "Asthma and Hay-Fever in Theory and Practice") and the chapter on pollens written by O C Durham for Feinberg's "Allergy in General Practice."

In the opinion of this reviewer, Dr Tuft's book is the most practical one so far written on the subject of allergy and should be of the greatest possible value to anyone interested in this field.

H M B

Syphilis Sive Morbus Humani By CHARLES S. BUTLER 137 pages, $23\frac{1}{2} \times 15$ cm
The Science Press Printing Company, Lancaster, Pa 1936 Price, \$3.00

This small volume has been written by the author as a summary of the evidence indicating, first, that syphilis was present in Europe long before Columbus and hence did not arise in America, and, second, that syphilis and yaws are different manifestations of the same disease. The results of prolonged historical research are evident on every page and the reader will be delighted by many picturesque quotations. The author's interest in his subject overflows into many allied fields so that topics such as the history of slavery are dealt with under sub-headings, and these diversions are almost always very interesting. Altogether the non-specialized reader will find enjoyment and profit in the reading of this little book and will acquire a broader view of the nature of the chief venereal infection.

M C P

COLLEGE NEWS NOTES

GIFTS TO THE COLLEGE

Grateful acknowledgment is made of the receipt of the following donations to the College Library of publications by members

Books

- Dr Charles Solomon (Associate), Brooklyn, N Y—"Formulary of the Jewish Hospital of Brooklyn"
- Dr August A Werner (Fellow), St Louis, Mo—"Endocrinology Clinical Application and Treatment"

Reprints

- Dr Nathan Blumberg (Fellow), Philadelphia, Pa—one reprint, "Bronchiectasis—with Description of the Peri Nasal Method of Introduction of Iodized Oil for Diagnosis and Treatment"
- Dr Milton A Bridges (Fellow), New York, N Y—ten reprints, "The Physician and Modern Dietetics", "Modern Dietetics and the Practitioner", "The Modern Approach to Diet Therapy", "The Primary Contracted Kidney", "Diet Prescription for the Tuberculous", "A Simple Method of Apothecary-Metric Transcription", "Fads and Fallacies Regarding Food and Diet", "Chronic Mucous Colitis", "The Relationship of Precordial Stress, Blood Uric Acid, and Salicylate Therapy", "The Present Status of Nutrition in Relation to Disease"
- Rear Admiral Charles S Butler (MC) U S N (Fellow), Washington, D C—four reprints, "Syphilis Sive Morbus Humanus", "Who Gave the World Syphilis? And How?", "The Importance of the Chancre in the History of Medicine", "A Glance at Results of the 'Last Thirty Centuries' of Venereal-Disease Prevention"
- Dr Anthony C Cipollaro (Associate), New York, N Y—two reprints, "Drug Eruptions", "Electrosurgery in Dermatology"
- Dr Harold G Trimble (Fellow), Oakland, Calif—two reprints, "What Is a Preventorium Child?", "Pneumoperitoneum in Treatment of Pulmonary Tuberculosis"
- Dr Willard R Wirth (Associate), New Orleans, La—one reprint, "Heart Disease and Pregnancy"

New Life Member—Dr Charles W Waddell (Fellow), Fairmont, W Va, by subscription became a Life Member of the American College of Physicians on September 7, 1937

Dr Louis H Fligman (Fellow and Governor for Montana for the College), of Helena, Mont, has been re-appointed a member of the Montana State Board of Health by the Governor of Montana. Dr Fligman has served on the Board since 1919, and acted as President four different times

Under the presidency of Rear Admiral P S Rossiter (Fellow), Surgeon General of the U S Navy, the Association of Military Surgeons of the United States held its Annual Convention in Los Angeles, October 14 to 16

Dr Julius H Hess (Fellow), Dr Robert A Black (Fellow), both of Chicago, and Dr Gerald M Cline (Fellow), Bloomington, Ill, have been named by the Governor of Illinois as members of a newly created Advisory Board of the Division for Handicapped Children, Illinois State Department of Public Welfare

Dr Arthur C Christie (Fellow), Washington, D C, was installed as President of the Fifth International Congress of Radiology at Chicago during September

Dr Charles A Waters (Fellow), Baltimore, was Chairman of one of the sessions on roentgen diagnosis, Dr Albert Soiland (Fellow), Los Angeles, and Dr Arthur U Desjardins (Fellow), Rochester, Minn, were Chairmen of sessions on radiotherapy, Dr George E Pfahler (Fellow), Philadelphia, gave the Caldwell Lecture of the American Roentgen Ray Society on "Treatment of Carcinoma of the Breast" Dr Pfahler also was an honorary vice president of the Congress Dr Benjamin H Orndoff (Fellow), of Chicago, was general secretary

Dr William C Menninger (Fellow), Topeka, Kan, delivered the Rogers Memorial Lecture on "Psychological Factors in Medical and Surgical Conditions" before the 96th annual meeting of the State Medical Society of Wisconsin, held in Milwaukee, September 15 to 17

Dr Logan Clendening (Fellow), Kansas City, Mo, was the banquet speaker at the above meeting, his subject being "The Great Centers of Medical Thought in the Past"

Dr Louis Hamman (Fellow), Baltimore, was one of the speakers in a symposium on non-tuberculous lung conditions at the annual meeting of the Southern Tuberculosis Conference and the Southern Sanatorium Association at Richmond, September 29 to October 1

Dr Edward J Murray (Fellow), Lexington, Ky, was President of the Conference

Dr Francis E Harrington (Fellow), Health Commissioner of Minneapolis, was recently appointed a member of the Hennepin County Sanatorium Commission, to succeed Dr S Marx White (Fellow)

Dr Samuel A Levine (Fellow), Boston, and Dr Cyrus C Sturgis (Fellow), Ann Arbor, Mich, will be guest speakers on the program of the fall clinical congress of the Oklahoma City Clinical Society, November 1 to 4

Dr Edward L Bortz (Fellow), Philadelphia, is Chairman of the Commission on Pneumonia Control of the Medical Society of the State of Pennsylvania

Dr Edward W Bixby (Fellow), Wilkes-Barre, Dr Clifford C Hartman (Fellow) and Dr George J Kastlin (Fellow), Pittsburgh, Dr Leon H Collins, Jr (Associate), Dr T Grier Miller (Fellow), Dr Henry K Mohler (Fellow), Philadelphia, are members of the Commission County medical societies were asked to create pneumonia control committees to be represented at a meeting of the Commission in Philadelphia during early October, when a campaign for the fall and winter was planned Points in the program will be to develop laboratories throughout the State for diagnostic typing and to have the State, in cases properly certified, furnish pneumonia serum to those unable to pay for it

The advisory board of the Pennsylvania State Health Department, at a meeting in July, adopted a regulation making pneumonia a reportable disease

Dr C Walter Clarke (Fellow), New York City, after completing his work with the New York City Department of Health, in the organization of its bureau of social hygiene, has returned to active duty with the American Social Hygiene Association as its Executive Director

Dr LeRoy H Sloan (Fellow), Chicago, has been appointed full Professor of Medicine in the University of Illinois College of Medicine

Dr Cyrus C Sturgis (Fellow), Professor and Head of the Department of Internal Medicine at the University of Michigan Medical School, has been appointed by the Dean to establish a clinic, and to supervise its operation, newly established at the University Hospital, Ann Arbor, through the Rackham Fund \$10,000.00 will be made available annually for a number of years to make a study of rheumatism

Dr John C Ruddock (Fellow), Los Angeles, addressed the 34th annual meeting of the Nevada State Medical Association, during September, on "Peritoneoscopy, Technic and Clinical Experiences"

Dr Warren C Breidenbach (Fellow), Dayton, has been appointed a member of the Ohio Public Health Council

Dr Carl V Weller (Fellow), Professor of Pathology, University of Michigan Medical School, Ann Arbor, delivered a series of postgraduate lectures in Lima, Ohio, September 20 to 24. The subjects included constitutional types in relation to disease, developmental disturbances of the face, mouth and neck, pathology of coronary occlusive disease, the thyroid gland, the gallbladder and the kidneys, parasitic worms of the North Central States, endometriosis, Antony von Leeuwenhoek and his microscopes

Dr Thomas T Sheppard (Associate), Pittsburgh, is a member of the committee appointed to supervise a trust fund of a million dollars given by Miss Emily Renziehausen to the Children's Hospital of Pittsburgh for "Perpetual research in the causes, treatment and cure of diabetes in the youth of the Pittsburgh area"

The first income from the fund is to be used in building an addition to the hospital to be known as the "Renziehausen Memorial Ward and Clinic". In addition to the fund, Miss Renziehausen donated an eleven-acre farm as a site for a home for convalescent children. Any part of the fund not needed for work on diabetes may be devoted to other research work or hospital service

Dr Frank L Roberts (Fellow), Trenton, Tenn, has been given charge of a newly established department of preventive medicine at the University of Tennessee School of Medicine. The department will be jointly supported by the University, the State Department of Health and the Tennessee Valley Authority

Dr Roberts will have the title of Professor of Preventive Medicine. He is a graduate of the University of Minnesota Medical School, 1922, was Health Officer of Gibson County from 1924 to 1928, Director of local health service in West Tennessee for the State Health Department from 1928 to 1930 and Director of Health Demonstrations for the Commonwealth Fund in Gibson County from 1930 to date

Dr Ernest S Mariette (Fellow), Oak Terrace, Minn, Dr J Burns Amberson, Jr (Fellow), New York City, Dr D O N Lindberg (Fellow), Decatur, Ill, and Dr Paul P McCam (Fellow), Sanatorium, N C, participated in the conduct of a symposium on sanatorium administration as a part of the program of the Mississippi Valley Conference on Tuberculosis and the Mississippi Valley Sanatorium Association, Dayton, Ohio, September 22 to 25

OBITUARIES

DR HENRY ROBERT MURRAY LANDIS

Dr Henry Robert Murray Landis (Fellow), a cultured, scholarly citizen and a distinguished, justly celebrated and highly esteemed physician of Philadelphia, died on September 14, 1937

Dr Landis was not only an expert clinician and a much sought after consultant but, in addition, he was a skilled and impressive teacher of medical art, a talented author and a recognized authority upon the diseases of the chest. In recent years Dr Landis has been seriously incapacitated by a chronic, complicated and distressing malady, and his death proved a welcome release from the vicissitudes of an intolerable existence from which the joy of living had long since departed. To those fully aware of the devastating and hopeless illness that he suffered, information that nature's final and infallible panacea, merciful endless sleep, had come to Dr Landis could only be greeted with a sigh of relief.

Dr Landis was known to his intimates as "Bob," "H R M L," or "Hiram," and the number of his admirers, both in and out of the profession, was legion. There will be many a sigh of heartfelt regret from colleagues, friends, patients and former students that such a kind and helpful physician should have become the victim of a relentless and pitiless fate.

H R M Landis was born in Niles, Ohio, in 1872. He was the son of Henry Gardner Landis, M D (1848-1886), who was born in Philadelphia, attended Yale University, where he received an A M degree in 1867, graduated from the Jefferson Medical College in 1870, served as an intern in the Philadelphia General Hospital (Old Blockley), entered practice in Niles, Ohio, and, a few years later, removed to Columbus, Ohio, where he became Professor of Obstetrics in the Starling Medical College. "Bob" Landis spent his childhood in Ohio, but secured his academic training at Amherst College, graduating with Calvin Coolidge in 1894. Following the example of his father, Landis attended the Jefferson Medical College and received his

degree in 1897 Again in his father's professional footsteps, he served his internship at the Philadelphia General Hospital, where he early revealed his talents and capabilities as an investigator, observer, clinician, reporter and literary critic

Dr Landis inherited a love for the best literature and from his school days onward he was recognized as a scholar of distinction The love of literature and the appreciation of the arts proved a wonderful escape from tedious realities when the ill fortune of illness came

At the completion of his internship Dr Landis established his practice in Philadelphia and at once became actively associated with the Medical Department of the Jefferson Medical College and Hospital In this institution Dr Landis came in contact with J Chalmers Da Costa, Hobart A Hare and other physicians who both intellectually and in medical science stimulated and inspired him An active service in the dispensaries supplied his inquiring mind with clinical problems and he found himself busied with both teaching and practice

In 1903 Dr Lawrence F Flick, the Nestor of American workers in the field of tuberculosis, was instrumental in incorporating and directing the Henry Phipps Institute for the Study, Treatment and Prevention of Tuberculosis Dr Landis was fortunate enough to be selected, with Dr Joseph Walsh, to take an active part in directing the studies, clinical and sociological, of this useful and justly celebrated organization

The White Haven Sanitarium for Tuberculosis (Luzerne County, Pa), another organization of Dr Flick's judicious planning, was fortunate enough to enlist the enthusiastic cooperation of Dr Landis, and for thirty years he gave to the patients of this hospital his skilled and efficient services Dr Landis was attending physician to the Department for Tuberculosis of the Philadelphia General Hospital for a number of years and resigned this position only when forced to do so by the stress of other duties When the Henry Phipps Institute became a part of the University of Pennsylvania School of Medicine, Dr Landis became the Director of the Clinical and Sociological Departments At this time, 1912, Dr Landis became the Professor of Clinical Medicine in the University of Pennsylvania School of Medicine, and occupied this position until his death

In 1917, in collaboration with Dr George W Norris, Dr Landis published a textbook, "Physical Diagnosis and Diseases of the Chest" The text, which entered its fifth edition in 1933, has been justly praised as the best single volume upon its subject matter The book is used in scores of medical schools and is a volume that is read alike by student, consultant and general practitioner

Dr Landis was elected to Fellowship in the College of Physicians of Philadelphia in 1904 and has been an active and interested Fellow in all that organization's activities The American College of Physicians elected Dr Landis to Fellowship in 1926 Unfortunately the state of his health prevented Dr Landis from meeting with the Fellows of the College as he would

have enjoyed doing. He was a member of the Association of American Physicians, the American Climatological and Clinical Association, the National Tuberculosis Association, the American Sanitarium Association and many other organizations.

Dr Landis was honored by his Alma Mater, Amherst College, in 1929, by being awarded the honorary degree of Doctor of Science. He is survived by his wife, Margaret Tucker Landis, whom he married in 1902.

The College has lost a distinguished Fellow, the medical world a clinician of exceptional ability and the poverty stricken tuberculous an interested and practical sociologist.

E J G BEARDSLEY, M D , F A C P ,
Governor for Eastern Pennsylvania

DR JOSEPH SAMENFELD

The death of Dr Joseph Samenfeld, of Brooklyn, N Y , occurred abroad on September 5, 1937, at the age of 61 years.

Dr Samenfeld was born in Brooklyn, and after attending public schools, he attended the Pratt Institute and the New York Preparatory School, before entering the University and Bellevue Hospital Medical College from which he graduated in 1903. Dr Samenfeld was for many years Chief of the Medical Clinic of the Jewish Hospital, Assistant, Associate and Attending Physician, St Catherine's Hospital, Attending Physician, Greenpoint Hospital, Consulting Physician, Williamsburg Maternity and Lutheran Hospitals, Member, Kings County Medical Society, New York State Medical Association, Williamsburg Medical Society, the American Medical Association and a Fellow of the American College of Physicians since 1923.

Dr Samenfeld volunteered for service in the World War and was commissioned a captain in the U S Medical Corps. He received a congressional medal for distinguished services. He is survived by a twin brother and six sisters.

The community and the profession have lost in Dr Samenfeld an untiring, diligent worker.

C F TENNEY, M D , F A C P ,
Governor for eastern New York

A Real Achievement

IN HIGHER CONCENTRATION and REFINEMENT of

SCARLET FEVER ANTITOXIN (NATIONAL)

(Refined and Concentrated Globulin)

Refinement and concentration of the pseudoglobulin fraction reduces volume 75 per cent and decreases serum reactions because of low content of foreign proteins

Lessens pain of injection

Smaller volume is more quickly absorbed

Gives quicker therapeutic response

Therapeutic Dose

Prophylactic Dose

SYRINGES SHOW EXACT SIZE

Each package of National Antitoxin or Curative Serum contains, as illustrated, an ampul vial of 1 to 10 dilution of serum to determine sensitivity of the patient by the cutaneous or scratch test

PROPHYLACTIC DOSE

2,000 Units U S Public Health Service (100,000 original neutralizing units) are contained in $\frac{1}{2}$ cc volume

THERAPEUTIC DOSE

6,000 Units U S Public Health Service (300,000 original neutralizing units) are contained in $1\frac{1}{2}$ cc volume

Each prophylactic or therapeutic dose contains 30 per cent excess units to insure potency beyond expiration date stamped on each package, and is furnished in sterile syringes, with rustless (chromium) steel needles

The advantages of a highly refined and concentrated Scarlet Fever Antitoxin should materially increase its use for prophylaxis of persons exposed to scarlet fever, and for the treatment of scarlet fever patients

THE NATIONAL DRUG COMPANY

PHILADELPHIA, U S A

New, Low-Cost Open-Top Oxygen Tent The COLLINS OXYFLO ACCEPTED

The Collins OXYFLO Open Top Oxygen Tent, accepted by the Council on Physical Therapy of the A M A, places oxygen therapy within the range of all

For the OXYFLO provides oxygen therapy that is basically as beneficial and efficient as the most expensive apparatus—yet the initial cost is approximately one third the cost of a large tent, and the average cost of operation is only from 15 to 20 cents an hour. So today there is no need for any hospital being without adequate equipment.

NO MOTOR, NO NOISE

Silent in operation, for there is no motor. No electrical connections required, either. The OXYFLO is simplicity itself.

So compact that it can be easily carried to a patient's home, either dismantled or ready to use. Ideal for use in the hospital or home.

MAIL COUPON FOR REPRINT

If you'd like to know more about the principles of operation of the Collins OXYFLO, let us send you one of a limited number of reprints of an article by Dr. Burgess, the originator. Just mail the coupon below.

ANNALS OF INTERNAL MEDICINE

OFFICIAL PERIODICAL OF THE AMERICAN COLLEGE OF PHYSICIANS

Place of Publication—Prince and Lemon Sts, Lancaster, Pa

Editorial Office—University Hospital,
Baltimore, Md

Executive Office—4200 Pine Street,
Philadelphia, Pa

THE ANNALS OF INTERNAL MEDICINE is published by the American College of Physicians. The contents consist of contributions in the field of internal medicine, editorials, book reviews, and a section devoted to the affairs of the College.

MANUSCRIPTS All correspondence relating to the publication of papers and all books and monographs for review should be addressed to the editor. No manuscripts will be accepted without his consideration. Bibliographic references are to conform to the following style.

4 Doe, J E. What I know about it, Jr. Am Med Assoc, 1931, xcvi, 2006-2008.

Six illustrations per article are allowed without cost to the author. Beyond this number the author must pay the actual cost of illustrations.

REPRINTS For each article published, there will be furnished gratis fifty reprints without covers. An order slip for additional reprints, with a table showing cost, will be sent with galley proof to each contributor. If additional reprints over the first fifty are wanted the order slip must be returned to the printer at the time corrected galley proofs are sent to the Editor.

REVIEWS The ANNALS will make an especial feature of the reviews of monographs and books bearing upon the field of internal medicine. Authors and publishers wishing to submit such material should send it to the editor. While obviously impossible to make extended reviews of all material, an acknowledgment of all books and monographs sent will be made in the department of reviews.

SUBSCRIPTION This periodical is issued monthly, new volumes beginning with the July number each year. Subscriptions may be by the volume or year, but the volume basis is especially recommended. Volumes will consist of approximately 1,400 pages. Subscription price per volume, or per annum, net postpaid \$7.00, United States, Canada, Mexico, Cuba, Canal Zone, Hawaii, Porto Rico, \$7.50, other countries. Prices for back volumes or numbers furnished upon application. Single numbers, current volume, when available, \$1.00. RADIATION THERAPY: Its Uses in the Treatment of Benign and Malignant Conditions

By I. I. KAPLAN, B.Sc., M.D.

This book is an exhaustive treatise on the uses of x-ray and radium. The fundamental principles of x-ray and radium physics are outlined in simple fashion and made practicable for both the radiation therapist and the physicist. The numerous conditions to which x-ray and radium have been applied are described in detailed steps so that the technics become comprehensible to the SURGEON, the PRACTITIONER, the STUDENT, and certainly the RADIATION THERAPEUTIST. The material available to the therapist and the varying technics employed are lucidly described so as to be easily adopted. Every ailment, whether benign or malignant, to which irradiation has been applied is carefully analyzed.

THE MANAGEMENT OF THE PNEUMONIAS

By JESSE G. M. BULLOWA, B.A., M.D.

This treatise represents actual experience in the care of almost 8,000 patients suffering from pneumonia. It is a careful study of etiology, diagnosis, prognosis and gives the principles of serotherapy and the precise directions in employing them. The principles of oxygen therapy with critical discussion of various methods are carefully analyzed. Present-day methods of treatment such as non-specific therapy with evaluation of the very new modality, sulfanilamide, complications, their occurrence, treatment and prevention are admirably treated. An entire section is given over to the discussion of pneumonia in children. This exceedingly practical book appeals to practitioner, specialist, student, and technician.

THE PHYSIOLOGY OF THE KIDNEY

By HOMER W. SMITH, A B., Sc.D., M.S.

In the preparation of this book the author has happily balanced the historical presentation of his subject with an authoritative, critical presentation of physiological principles. The first part deals with the history and principles of renal function, and the excretion of waste products in terms of renal clearances. The second part is concerned with the electrolyte pattern of the plasma, and the problems of salt and water equilibria. The third part consists of a full treatment of the excretion of water, including the important subjects of the nervous control of renal activity and the action of diuretics. The author's experience in the study of the comparative physiology of the kidney, combined with the numerous investigations which have been carried out in his laboratory on the renal function in man, enables him to present the first broad and well integrated resume of this field. **THE PHYSIOLOGY OF THE KIDNEY** is a volume which makes its appeal to the student, the investigator, and the clinician.

ORTHODIASCOPY

An Analysis of Over Seventeen Hundred
Orthodiascopic Examinations

This method, which the author uses in every heart examination, determines heart size and detects early stages of cardiac enlargement, and reveals certain easily distinguishable changes in the shape of the cardiovascular shadow characteristic of various types of heart disease. None of the short articles on this subject which have appeared in the literature have attempted to describe the apparatus used or the details of procedure in such a way as to enable the physician unfamiliar with the method to develop the technique of orthodiascopy. One of the chief purposes of this monograph is to present this phase in simple and practical form. One chapter is devoted to the correlation between the common physical signs and the orthodiascopic findings lending new significance to the ordinary procedures employed by the average physician in his everyday office work.

LEUKEMIA AND ALLIED DISORDERS

*Ready
in
January
Probably
\$5 00*

This volume fills a long felt need for a comprehensive monograph on leukemia. The disease is poorly understood and there has been much confusion regarding terminology, classification, etiology, natural history of the disease and its pathologic physiology. In this book the fundamental aspects of the problem are discussed with special reference to the pathologic physiology of the blood and the blood-forming organs and its bearing on the structure and function of the organism as a whole.

Jones

DIGESTIVE TRACT PAIN

Diagnosis and Treatment

In accurate diagnosis and treatment of gastro-intestinal disorders, pain is the outstanding symptom which the patient presents. This book gives a study on pain and other similar sensations caused by disturbances of the digestive tract, and experimental observations on pain produced at various levels throughout the entire digestive tract in given individuals are here recorded for the first time. In addition to this study, the author has added a group of clinical observations having a direct bearing upon the production and diagnosis of alimentary tract pain.

BUFFERED ALKALINIZATION by the safe, physiological process

WHERE buffered alkalinization is desirable—as during sulfanilamide administration, in the treatment of colds, influenza and other seasonal respiratory affections—Kalak offers these clinical advantages

(1) It presents a balanced combination of bicarbonates in solution (2) It contains the mineral substances normal to the blood (and no other)

Kalak's high buffering value helps to maintain the urinary pH of 7.4 which has been found so desirable in sulfanilamide therapy

KALAK

is synthetically prepared—is hypertonie, uniform in composition, definite in alkali potency

PROTAMINE INSULIN IN DIABETES

NEW (6th) EDITION

JUST READY

THE TREATMENT OF DIABETES MELLITUS

By ELLIOTT P. JOSLIN, M.D., F.A.C.P.

Clinical Professor of Medicine, Harvard Medical School, Etc

With the cooperation of

Howard F. Root, M.D., Priscilla White, M.D., and Alexander Marble, M.D.

Octavo, 707 pages, illustrated Cloth, \$7.00, net

THE discovery of protamine insulin, marking the beginning of a new era for the diabetic, has necessitated a complete revision of this standard work. Two new chapters indicate how to transfer the patient from regular insulin to protamine insulin without danger. The author and his associate here report their successful experience in more than 1,200 cases in which protamine insulin has been used. This edition summarizes all of the new factors in the treatment of the disease and records the vast progress that has been made. It presents a combination of scientific and clinical experience which is unequalled.

NEW (6th) EDITION

JUST READY

A DIABETIC MANUAL

By ELLIOTT P. JOSLIN, M.D., F.A.C.P.

Clinical Professor of Medicine, Harvard Medical School, Etc

12mo, 219 pages, illustrated with 48 engravings and a colored plate Cloth, \$2.00, net

THIS work has always been an important contribution to the education of the diabetic patient. The present edition is unusually important in that it describes the improvement in treatment through the use of protamine insulin. It passes on to the patient the new knowledge so essential to the effective use of the new insulin. It clarifies the doctor's instructions and simplifies diet and calculation. Many physicians and hospitals purchase this medical classic in quantities for distribution to their patients. This manual should be the physician's first prescription for the diabetic.

THE PATIENT AND THE WEATHER

By

WILLIAM F. PETERSEN, M.D.

With the assistance of

MARGARET E. MILLIKEN, S M.

VOLUME IV—PART 2

Integrating FORM, FUNCTION AND ENVIRONMENT, in Disease

HYPO AND HYPERTHYROIDISM

The first section links the more highly differentiated human types (pyknic and leptosome) and the extremes of divergent endocrine dysfunction. Detailed day-by-day studies are presented of the sluggish reaction of the cretin to the environment (weather, diet, emotions, etc.) by contrast to the effect on the more sensitive person. The importance of iodine loss is stressed as well as the role of relative anoxia of the thyroid gland itself in the development of unusual irritability.

DIABETES

The significance of environmental alterations for the entire chain of integrative autonomic organs involved in the mechanism of diabetes—hypophysis, adrenal, pancreas, thyroid, the liver—the blood balance between the splanchnic and peripheral organs, is involved. Diabetes is discussed as a disease of northern man, first, as a dysfunction in the youthful leptosome and finally as a manifestation in the adult pyknic type, in whom the vascular integration becomes inadequate with advancing age.

GRANULOPENIA AND THE BLOOD DYSCRASIAS

Here the reflection of vascular instability in bringing about diametrically opposite functional results, for instance, granulopenia on the one hand and leukemia on the other, is illustrated. Day-by-day studies of blood morphology reveal the absolute concordance of bone marrow response and the environmental situation.

TUBERCULOSIS

The disturbance of the symbiosis of the tubercle bacillus and the host with change in the metabolic status of the tissues is illustrated in detailed studies of chronic and acute cases of tuberculosis. The basis for spring activation and of summer and autumn quiescence is detailed in day-by-day studies extended over long periods of time. The exact dependence of subjective and objective symptomatology on the metabolic phase fluctuation of the host is demonstrated and this in turn is presented as it reflects change in the environment.

Helping
the patient
who cannot
sleep

● The use of sedatives is not always necessary—nor always advisable. However, there are many cases where the use of a safe sedative will often prove helpful. This is particularly true during serious illness or before surgical procedures where sleep is essential to conserve the physical resources of the body.

In the selection of a sedative or hypnotic due consideration must be given to its safety, its therapeutic benefits and its freedom from undesirable after effects.

IPRAL CALCIUM has long been used as a safe sedative and hypnotic. It is readily absorbed, effective in small dosage and rapidly eliminated, producing a sound, restful sleep from which the patient awakens calm and generally refreshed. In the usual therapeutic doses no untoward systemic by-effects have been reported. Undesirable cumulative

effect may be avoided by proper regulation of the dosage.

IPRAL CALCIUM (calcium ethylisopropylbarbiturate) is supplied in 2-gr tablets and in powder form for use as a sedative and hypnotic.

IPRAL SODIUM (sodium ethylisopropylbarbiturate) is supplied in 2-gr capsules for hypnotic use and in 4-gr tablets for preanesthetic medication.

IPRAL CALCIUM (Powder) is available in 1-oz bottles. Tablets Ipral Calcium 2 gr, Tablets Ipral Sodium 4 gr, and Capsules Ipral Sodium 2 gr are available in bottles of 100 and 1000.

AS WITH ALL FINE INSTRUMENTS

So It Has Been With The G-E Electrocardiograph

Making it smaller has made it more convenient without any sacrifice in accuracy or dependability

It is a *great* instrument, this new light-weight, low-cost electrocardiograph, beautiful, too, in its streamlined, all-metal, shielded case

Great, we say, because while it is priced to be within the reach of most practitioners and institutions, *it is built to endure*, to give the kind of service you have a right to expect, to *produce records consistently that are accurate and of true diagnostic value*. No skimping in construction in order to whittle down manufacturing costs, no inferior component parts liable to cause embarrassing breakdowns. Instead, such care in building and choice of materials that dependable and economical operation is made inherent.

The principle of thermionic amplification is retained, we introduced it in the field of electrocardiography and so far no better means of amplifying the minute current of the heart has been found. The new G-E Electrocardiograph incorporates its own power supply to make it independent of commercial electric current and to assure consistent smoothness of recording. Every modern refinement is included to make for simplicity of operation and accuracy of results.

It is portable—but not at the expense of ruggedness. It is compact—but not at any

sacrifice of proper internal construction. It is the famous G-E Electrocardiograph which you have admired and desired made smaller in size and lower in price.

See it, inspect it inside and out; operate it. Make a test record to convince yourself that it is *fine* mechanically, electrically, and clinically.

To do these things in no way obligates you. Merely mail the handy coupon—*today*.

Announcing

PERTUSSIS ANTIGEN (Detoxified)

Lederle

THIS new form of therapy is recommended for the treatment of active cases of Whooping Cough as well as in general prophylaxis.

Free from bacterial cells, Pertussis Antigen (Detoxified) *Lederle* is a departure from the usual form of vaccine therapy. Based upon a toxic principle derived from *H. pertussis*, treatment with formalin converts the toxic factor into a non-toxic substance having antigenic properties.

If used early in *treatment* or soon after exposure, the immunological response is sufficiently rapid to modify or prevent, respectively, the disease in the majority of cases, as evidenced by the following:

49 of 53 cases treated during the first or second week did not develop whooping or vomiting.

Of 70 cases treated during the third or fourth week, 30 became symptom-free after the completion of injections, while the remainder showed marked improvement but continued to run a mild, modified course of whooping cough. Cases treated during the fifth week showed no benefit.

When used for *prevention*, only 3 out of 140 developed the disease and those 3 were mild atypical cases.

LOWER MORTALITY QUICKER RECOVERY

Reduction in mortality, quicker recovery, and lowered incidence of complications have followed use of Meningococcus Antitoxin, P D & Co, in epidemic (meningococcal) meningitis. The reduction in mortality has, in certain series, approximated fifty per cent.

Meningococcus Antitoxin can be given intravenously, intramuscularly, and intraspinally. Experience indicates that the in-

travenous route is the most rapidly effective and that it should be used initially, intraspinal and intramuscular injections, supplementing intravenous administration, to be made when conditions so indicate.

Meningococcus Antitoxin was developed in the Research Laboratories of Parke, Davis & Company, and was introduced to the medical profession in 1934. It is supplied in container with diaphragm stopper at each end, each container holding approximately 30 cc. and representing at least 10,000 units.

Diabetic

LIVE LONGER TODAY

THE LIFE SPAN of the diabetic has been lengthened considerably following the discovery of Insulin and the growing knowledge of its use. There is, however, a definite responsibility on the part of the physician to educate the many new diabetics in the importance of proper diet and proper use of Insulin preparations.

The apparent increase in diabetes in recent years has been attributed to the modern manner of living, increased sugar consumption, overeating and lack of muscular exercise. With proper management the great majority of patients can be kept well-nourished, sugar-free, and at work.

Insulin Squibb is an aqueous solution of the active anti-diabetic principle obtained from pancreas. It is accurately assayed, uniformly potent, carefully purified, highly stable and remarkably free of pigmentary impurities and proteinous reaction-producing substances.

Insulin Squibb of the usual strengths is supplied in 5 cc and 10 cc vials.

Protamine Zinc Insulin, Squibb complies with the rigid specifications of the Insulin Committee, University of Toronto, under whose control it is manufactured and supplied. It is available in 10-cc vials. When this preparation is brought into uniform suspension, each cc contains 40 units of Insulin together with protamine and approximately 0.08 mg of zinc.

The Aseptic Surgical Field

● The basic requirement of modern surgery is asepsis. The choice of a suitable antiseptic is hardly less important than cleanliness and proper handling of instruments and supplies.

Bactericidal action may be obtained without undue tissue damage by the use of 'Merthiolate' (Sodium Ethyl Mercuri Thio-salicylate, Lilly). This antiseptic is suitable for all surgical indications and may be used to advan-

tage in both clean and contaminated wounds.

Tincture 'Merthiolate,' an alcohol-acetone-aqueous solution, 1:1,000, is recommended for pre-operative preparation of the intact skin.

Solution 'Merthiolate,' an isotonic aqueous dilution, is suggested for open wounds and for application in body cavities.

Supplied in four-ounce and one-pint bottles.

ELI LILLY AND COMPANY

Principal Offices and Laboratories, Indianapolis, Indiana, U S A

A New Method to Treat Dropsy

SIMPLE • SAFE • EFFICIENT

*C*ritical investigators have found Mercurin Suppositories to be as efficient as the parenterally administered mercurial diuretics. Experienced cardiologists recommend Mercurin Suppositories in the treatment of Edema of Congestive Heart Failure, Nephrosis, and Cirrhosis of the Liver with Ascites because the rectal administration of Mercurin is simpler and safer than the injection of mercurial diuretics.

EFFICIENT LUMINAL THERAPY

—even when
oral use is
impossible

STATUS EPILEPTICUS
ACUTE PSYCHOSIS
DRUG ADDICTION
VOMITING of PREGNANCY

ORDINARILY the administration of Luminal or Luminal Sodium in tablet form fully meets the requirements in epilepsy and other affections where sedative and antispasmodic medication is indicated. Tablets of various sizes are available for such purposes.

Under certain conditions—status epilepticus, acute psychosis, drug addiction, vomiting of pregnancy, etc—it is necessary to resort to the subcutaneous, intramuscular or intravenous route.

Aqueous solutions of Luminal Sodium for injection are readily made by the use of Luminal Sodium ampules, which contain 2 or 5 grains of the sterile powder. For intramuscular injection, Luminal Sodium in Ethylene Glycol is most convenient.

HOW SUPPLIED For subcutaneous or intravenous injection, Luminal Sodium in 2 or 5 grain ampules, boxes of 5, 25 and 100. For intramuscular injection, Luminal Sodium in Ethylene Glycol in 2 cc ampules (5 grains), boxes of 5 and 100. For oral administration only, Luminal Sodium in tablets of $\frac{1}{4}$ and $\frac{1}{2}$ grain, bottles of 100, and tablets of $1\frac{1}{2}$ grains, bottles of 50.

Write for informative 24 page booklet in which the following subjects are comprehensively outlined: Indications, Action, Dosage and Manner of Use, By-Effects, General Therapeutic Uses.

HAVE IT DOWN IN "BLACK AND WHITE"

The BENEDICT-ROTH Metabolism Apparatus gives you all the advantages of a *written record*, from ORIGINAL TRACING to FINAL RESULTS

The Benedict Roth pioneered graphic respiration tracings for greater accuracy in metabolism testing. Today non graphic apparatus is practically obsolete.

To give you the advantages of a *written record* of the whole test, the Benedict Roth chart provides ALL the data needed for computing the B M R.

Simple Computations

Space is provided for computations which are so simple that they require only two or three minutes. When you have finished, you have a COMPLETE, PERMANENT RECORD in BLACK AND WHITE of *every thing* relating to the final result which is your guide in deciding the proper treatment for your patient.

"Gadgets" and devices intended to simplify computations have an undemable appeal. They may possibly save a small amount of time each day—so small that it is negligible. Besides, one is confined to a single method of computing the B M R.

Choice of Standards

With the Benedict Roth, the DuBois norms, printed on the charts, are entirely satisfactory for most cases. But one can also use the Harris Benedict or any other standards with ease, and there is a distinct tendency among metabolism authorities to report results on the basis of more than one "normal standard."

If you are not already using a Benedict Roth, send for one of our sample charts illustrating the advantages of the BLACK AND WHITE record.

MAIL THE COUPON NOW!

INCREASED VITAMIN A EFFICACY

When Cod Liver Oil is Emulsified with Maltine

Carefully controlled laboratory tests on animals indicate that the vitamin A value of cod liver oil is enhanced *twofold* when it is emulsified with Maltine. MALTINE WITH COD LIVER OIL includes the elements of both ingredients—vitamins A and D plus other valuable components from cod liver oil, as well as all the desirable factors contained in Maltine. This 62-year-old preparation offers the physician a convenient method of prescribing these elements in an easily taken and palatable form. Patients—even small children—like MALTINE WITH COD LIVER OIL because it does not have the unpleasant oily consistency usually found in vitamin-bearing oils.

Another preparation which has also found favor with the medical profession is MALTINE WITH COD LIVER OIL and IRON IODIDE. This product contains two grains of freshly prepared iron iodide per fluid ounce. The Maltine Company, 60 Hudson Street, New York.

WITH COD LIVER OIL
INTRODUCED 1875

Now Ready —

Soluble gelatin capsules in boxes of 25 and 100

Not advertised to the public

IN PREGNANCY AND LOW-CALORIE DIETS

and wherever vitamins A and D are required with minimum added calories

RESTRICTED diet regimens, as for the obese, know no season for vitamin therapy. Because of the frequent drain on the mother's stores and the added requirement of the fetus, the need for vitamins A and D is increased during pregnancy. Yet, it is in just such cases that there may be an aversion or intolerance to fats. In the obese, who studiously avoid butter, cream and other good sources of vitamin A, the deficiency should be made up. This can be

done in a convenient and highly acceptable manner by prescribing Mead's Capsules of Oleum Percomorphum, which combine a high potency of both vitamins A and D. Each 10-drop capsule supplies natural vitamins in amounts not less than 13,300 A units and 1,850 D units (U S P). Every capsule represents more than 5 teaspoonfuls of cod liver oil* in vitamins A and D. These vitamins, moreover, are in the same ratio as in cod liver oil*.

*U S P XI Minimum Standard

For physicians who prefer Mead's Viosterol in Halibut Liver Oil, 3-minim capsules containing not less than 8,500 vitamin A units and 1,700 vitamin D units (U S P) are available.

THYROID-PITUITARY RELATIONSHIP IN DIABETES INSIPIDUS *

By THOMAS FINDLEY, JR, M D, *St Louis, Missouri*

ALTHOUGH it has long seemed reasonable to attribute diabetes insipidus to hypofunction of the posterior pituitary it has, until recently, been difficult to understand why lesions limited to the hypothalamus can establish the condition and why on the other hand experimental hypophysectomy does not. The modern theory of diabetes insipidus, as expressed by Ranson and his collaborators whose own brilliant researches¹⁻⁹ have contributed so much to its conception, goes far toward reconciling such inconsistencies as these and provides at least a working hypothesis susceptible of experimental and clinical demonstration. It rests upon the recent fundamental discovery of a bundle of non-myelinated nerve fibers which arise in various parts of the hypothalamus and descend the pituitary stalk to terminate in the posterior lobe of the hypophysis and also possibly in the intermediate lobe. Detailed accounts of these anatomical studies are contained in the writings of the Chicago group^{1, 2, 4, 6, 7}. Their functional implications are at once apparent when it is seen that a permanent polyuria comparable to diabetes insipidus has been produced in the rat, cat, dog and monkey by bilateral interruption of this so-called hypothalamico-hypophyseal tract, (a) at the supraoptic nuclei¹⁰, (b) along the course of the tract either in the anterior hypothalamus^{1, 2, 4, 11, 12, 13, 14, 15} or in the pituitary stalk^{16, 17, 18, 19, 20}, or (c) in the posterior lobe itself^{16, 21, 22}. That this tract influences the secretory activity of the posterior pituitary is strongly suggested by the facts that experimental injury to the hypothalamic nuclei or to the tract itself is followed by degeneration of the tract distal to the site of trauma,^{2, 10, 17, 23} by atrophy of the posterior lobe (Broers¹⁰ even observed homolateral atrophy after destruction of one supraoptic nucleus), and by a greatly diminished concentration of pressor, oxytocic and antidiuretic material in extracts of the posterior lobe^{7, 8}. Presumably the impulses which reach the posterior lobe from the

* Read at the St Louis meeting of The American College of Physicians, April 19, 1937
From the Department of Medicine, Washington University and Barnes Hospital, St Louis, Mo

floor of the third ventricle are secretory in nature and this form of polyuria is essentially paralytic rather than irritative in origin since the permanently excessive urine flow follows the causative lesion only after a latent period of one to two weeks⁴. If one excludes the transient polyurias observed by Claude Bernard and successors after injury to the floor of the fourth ventricle, on the apparently justifiable grounds that they are due to vasomotor adjustments or to indirect stimulation of the pituitary, the fact remains that permanent polyuria has been produced only by lesions located somewhere along the supraoptico-hypophyseal tract. Thus a reasonable explanation is afforded for the fact that extrapituitary lesions can result in a condition remediable by extracts of the posterior lobe itself, and the clinical portent of such disturbances as skull fracture, encephalitis, suprasellar tumor and basilar meningitis is plain.

Were this the entire story, however, it is obvious that total hypophysectomy or clinical lesions which destroy the whole gland would likewise result in diabetes insipidus. There must be another essential factor, and von Hann²⁴ is given credit for first suggesting that the disease cannot occur unless functioning anterior lobe tissue is present. In a considerable number of clinical autopsies, all marked by destruction of the posterior lobe of the pituitary, he pointed out that the only ones with diabetes insipidus were those with viable anterior lobe tissue. This astute observation has been supported by those who have consistently produced permanent polyuria in the dog and rat by simple extirpation of the posterior lobe^{16, 21, 22}. Although many early investigators reported that polyuria frequently occurred after total hypophysectomy it is generally believed now that these transient increases in urine volume are not comparable to diabetes insipidus^{*} and that uncomplicated excision of the entire hypophysis is not a cause of polyuria²⁵.

Thus a state of normal water balance seems to be in part dependent upon a balance between the diuretic property of the anterior and the antidiuretic activity of the posterior lobes. That extracts of anterior lobe tissue evoke diuresis has been repeatedly demonstrated,^{26, 27, 28, 29, 30} and Pencharz, Hopper and Ryneanson²² have produced transient oliguria in rats by excision of the anterior lobe alone. In this respect as in others, however, the activity of the anterior lobe is complicated by interglandular relations. Biasotti²⁸ and White and Heinbecker³⁰ have confirmed the finding of Barnes, Regan and Bueno²⁷ that anterior lobe extracts do not produce diuresis in thyroidectomized dogs. Mahoney and Sheehan²⁹ found that the polyuria which followed crushing of the pituitary stalk in dogs was promptly and completely abolished by thyroidectomy and rapidly reestablished by feeding desiccated thyroid, it should be noted, however, that these polyurias were not assuredly permanent and that enormous doses of thyroid were used. Fisher and Ingram⁵ then showed that the more permanent polyurias following

* Transient postoperative polyurias may well be due to vasomotor readjustments, to the greater stability of circulating anterior lobe hormone, or to unintentional stimulation of the anterior lobe or pars tuberalis, as evidenced by the experiments of Ingram and Barris³.

hypothalamic puncture in cats were greatly diminished though not abolished by thyroidectomy, and White and Heinbecker³⁰ reported that the transient post-hypophysectomy diuresis in dogs was quickly abolished by the same procedure. Heinbecker and White¹⁵ have several times observed that the permanent polyuria caused by hypothalamic injury in dogs is diminished by thyroidectomy to about the same extent as that in Fisher and Ingram's cats.

In two species, then, the diuretic property of the anterior pituitary is modified by thyroid activity, and the rapidity with which urine flow parallels thyroid administration or withdrawal suggests that the mechanism is not wholly explained by variations in the rate of tissue oxidation. It has been claimed that the diuretic and thyrotropic principles of the anterior pituitary are identical.²⁷ Gaebler,³¹ however, observed no correlation between the changes induced in the water metabolism of his almost completely thyro-parathyroidectomized dogs by anterior lobe extracts and the variations in basal metabolic rate. Dix, Rogoff and Barnes³² found that neither anterior lobe extracts nor thyroid substance induced diuresis in depancreatized dogs despite the usual elevations in pulse and basal metabolic rate, and White and Heinbecker³⁰ felt that the diuretic and thyrotropic hormones could not be identical because anterior lobe extract, ineffective in thyroidectomized dogs, produced diuresis when combined with thyroid in doses too small to increase urine flow when the thyroid was given alone. Regardless of the exact identity of this diuretic principle in the anterior pituitary, however, it is of further importance to decide whether changes in water output induced thereby are due to a specific water-regulating substance elaborated in the thyroid or whether they are due simply to the generalized acceleration in tissue metabolism. Even should it be proved that the thyrotropic hormone, working through the thyroid, is responsible for the diuresis the possibility still remains that the thyroid itself exerts an effect on water exchange distinct from that on tissue respiration.

Similar studies not having been reported on man or monkey, it was decided to perform total thyroidectomy on a human subject with diabetes insipidus to determine if possible (1) the effect on urine flow under controlled conditions, (2) whether his sensitivity to pitressin might thereby be increased and (3) whether thyroid and other metabolic stimulants affect water exchange in different manners. We were aware, of course, that species differences might result in a disappointing reduction in urine flow.

There were other but less compelling reasons for believing that ablation of the thyroid might materially lessen urine output. The occasionally striking diuretic efficiency of thyroid substance has long been known. Eppinger³³ described the opposing effects which thyroidectomy and thyroid administration have upon the renal elimination of water and sodium chloride and showed how the rate of absorption of saline from subcutaneous tissue paralleled the rise in metabolic rate induced by thyroid. Dietel and Ditsch³⁴ claimed that pituitrin and thyroxin exert antagonistic changes in the elec-

trolyte distribution of various tissues, and others have shown ³⁶ how thyroxin accelerates the interchange of salts and water between tissues and blood. Most of those who have studied the effect of thyroidectomy upon the pituitary have emphasized the anterior lobe hypertrophy ²⁵ but Herring, ³⁷ who thought that the hyaline material in the posterior lobe might represent pituitrin in visible form, found this material greatly increased after thyroidectomy, although later ³⁸ he reported that removal of the thyroid did not enhance the physiological potency of posterior lobe extracts. A specific effect of posterior lobectomy upon the thyroid apparently has not been found nor has the thyroid in clinical diabetes insipidus been described as visibly abnormal. Pal ³⁹ claimed to get beneficial results in Graves' disease from injections of pituitrin, Gottdenker ⁴⁰ described an antagonism between pituitrin and the thyrotropic hormone, and Peczenik and Popper ⁴¹ reported that pituitrin prevents the thyroid hyperplasia due to anterior lobe hormone. Strauss ⁴² once observed clinical diabetes insipidus disappear with the onset of spontaneous myxedema.

In brief, then, the von Hann-Richter-Ranson theory holds that diabetes insipidus is due to hypopitressinemia in the presence of a diuretic hormone from the anterior pituitary. It is admittedly not a perfect hypothesis but no other has been proposed which harmonizes so many facts and against which there are so few objections. Some of the objections which have been raised are negative ones in the sense that they represent real gaps in our knowledge of pituitary physiology e.g., the pars tuberalis is so closely adherent to the base of the brain as to make complete hypophysectomy to date an impossible achievement. Atwell ⁴³ has attributed certain diuretic effects to extracts of the pars tuberalis but the function of this structure is virtually unknown. Similarly, it has been impossible to extirpate the pars intermedia alone or to remove the posterior lobe cleanly from it but Fisher's tissue assays ⁸ in experimental diabetes insipidus make it appear unlikely that this portion of the gland has anything to do with mammalian water metabolism.

On the positive side there are certain observations which prevent unqualified acceptance of the modern theory. It has been claimed ^{11, 44, 45, 46} that hypothalamic injury will produce diabetes insipidus in a previously hypophysectomized animal, a phenomenon which if true almost certainly eliminates hormonal participation. White and Heinbecker ³⁰ have reviewed the evidence for this statement and conclude that it does not deserve complete support because the protocols lack adequate proof that anterior lobe tissue was absent or because the resulting polyurias were brief and possibly spontaneous. In view of such claims, however, it has been suggested that after hypophysectomy the tuber cinereum and hypothalamus vicariously assume the rôle of pituitrin manufacture ⁴⁷ but the previously mentioned biological assays make this appear improbable, ⁸ and the impossibility of removing all of the tuberal and anterior lobe cells suggests that these post-

hypophysectomy punctures may have served only to stimulate production of diuretic material

Again, if polyuria is due to the unrestrained diuretic effect of the anterior pituitary it is difficult to understand why extracts of this lobe do not induce diuresis in normal rats or increase the polyuria of hypophysectomized rats⁴⁸ and why implants of fresh tissue from the same source do not increase urine flow in hypophysectomized rats²²

Mahoney and Sheehan²³ found that diabetes insipidus could be produced by clipping the pituitary stalk in dogs but not in monkeys, they point out, however, that the monkey differs from the dog in that it is much easier to sever his stalk without hypothalamic injury than it is the dog's, that the nerve tracts in the stalk are more poorly developed, and that differences in blood supply probably account for the fact that stalk occlusion does not induce the same amount of posterior lobe atrophy that it does in dogs

More recently Keller, Noble and Hamilton⁴⁹ reported that in five dogs they severed the stalk at its junction with the hypothalamus without injury to the anterior lobe, the pars intermedia or the hypothalamus and with minimal damage to the pars tuberalis, in several animals a slight increase in water consumption followed but none developed diabetes insipidus. Subsequent cauterization of the "proximal surface" of the separated gland induced marked polyuria, which soon disappeared in four dogs, and remained as a permanent diabetes insipidus in one. They also terminated a chronic hypothalamic polyuria by removal of the pituitary, an experiment reminiscent of Crowe, Cushing and Homans' early finding⁵⁰ that if anterior lobe tissue were immediately transplanted into hypophysectomized dogs polyuria continued until the transplant was removed*. The inconsistent feature of this report is the non-appearance of polyuria after denervation of the posterior lobe. The authors' description seems to indicate that, due perhaps to a more intact blood supply, there was less functional impairment of the separated gland than has usually occurred. This does not invalidate the conception that diabetes insipidus is in part due to hypopitressinemia but may indicate that destruction of the supraoptico-hypophyseal tract does not produce the same degree of posterior lobe insufficiency in the dog that it does in the cat.

Reference should also be made to the paradoxical capacity of certain subjects with diabetes insipidus to retain water⁵¹ and salt⁵². The German school has long maintained that the disease is due to inability of the kidneys to concentrate electrolytes, a defect readily explainable by the hypopitressinemia theory, but it is less understandable why at least some individuals with diabetes insipidus should retain extra salt and water for long periods of time under conditions which should permit maximum excretion³⁴.

Finally, and perhaps most puzzling of all, is the refractoriness of some diabetes insipidus subjects to pituitrin. Biggart's suggestion⁵³ that pituitrin

* In a subsequent paper¹⁶ Cushing said that the same phenomenon accompanied transplantation and removal of posterior lobe tissue. So far as can be determined these conflicting observations have not been reconciled.

is effective only in the presence of intact hypothalamic nuclei apparently no longer holds, but the modern theory also offers no plausible explanation unless one is prepared to believe that diabetes insipidus can exist as the result of a chronic stimulus to diuresis arising in the pituitary

So far as the thyroid is concerned, it is not clear why thyroidectomy abolishes the transient experimental polyurias and only partially inhibits the permanent ones. In any event, it is not thought that the thyroid plays more than a secondary rôle in clinical diabetes insipidus but it is hoped that the observations reported below show that its diuretic effect, limited as it is in humans, is not due solely to its capacity to accelerate cellular metabolism

CASE REPORT

W. D., a 55-year-old male negro, entered Barnes Hospital in the summer of 1936 complaining of polydipsia and polyuria of one year's duration. His previous health had been good, and the physical examination was unimportant except for moderate obesity and hypertension.

Laboratory Data Blood count erythrocytes 5,010,000, hemoglobin 105 per cent, leukocytes 6,400, eosinophiles 5 per cent, basophiles, myelocytes and juveniles 0 per cent, stabs 3 per cent, segmented 55 per cent, lymphocytes 33 per cent, monocytes 4 per cent. The urine was normal but on an unrestricted ward diet each 24 hour output averaged about 10 liters with a usual specific gravity of 1.002. Blood Kahn reaction, 4 plus. Lumbar puncture yielded a clear fluid under normal pressure containing 4-6 lymphocytes per cu mm, a 2 plus Wassermann reaction, a colloidal gold curve of 2545555500, and protein content of 110 mg per cent but a negative Pandy. Basal metabolic rate, minus 16 per cent. Plasma cholesterol 292 mg per cent. Visual fields and roentgen-ray of the pituitary region negative.

Methods The patient was placed on a diet containing less than 2 gm of sodium chloride daily, extra salt was given him in a weighed shaker and the daily intake calculated by assuming that the diet contained 2 gm and adding to this whatever salt was not returned in the shaker. It is believed that the recorded figures are accurate to less than 1 gm daily. He was allowed to eat as much as he wished but the actual daily intake of protein, fat and carbohydrate was carefully weighed*. He usually consumed about 75 gm of protein and 2000 calories daily.

Total thyroidectomy was performed by Dr. Peter Heinbecker on August 1, 1936⁵¹. Figure 1 is a section from the removed gland. The extreme resting phase may perhaps be correlated with the basal metabolic rate of minus 16 per cent but it is interesting to note that the pathologist on his initial report remarked that the appearance was not unlike that of thyroids from hypophysectomized animals.

Chart 1 depicts the water and sodium chloride output before and after thyroidectomy, the postoperative figures were obtained after the basal metabolic rate had fallen to an apparently constant low level of minus 35 to 40 per cent and the plasma cholesterol had risen to 490 mg per cent. Unfortunately urinary nitrogen was not determined until the day of operation. Comparison of periods 1 and 6 when the diet contained an excess of salt shows that the average daily urine output had fallen by about 2 liters, a result similar to the finding of Fisher and Ingram⁵ that thyroidectomy diminished the diuretic effect of sodium chloride in cats with experimental diabetes insipidus. Periods 2 and 7 show an increased response to pitressin after operation although the figures are not strictly comparable because of the greater salt intake during the preoperative interval. In periods 3 and 8, when the salt intake had been re-

*I am heavily indebted to Miss Isabel Grasser for her meticulous supervision of the diets

duced to 5 gm daily, it is seen that the average urine output in the two periods is practically identical, leading to the conclusion that in this instance thyroidectomy was no more effectively antidiuretic than a low salt diet. Periods 4 and 9 are believed to be comparable and again show that after operation the patient's sensitivity to pitressin was appreciably increased. Stern and Gilligan⁵⁵ had found that individuals with artificial myxedema were no more sensitive to pituitrin than normals. In period 5 desiccated thyroid in doses sufficient to raise the basal metabolic rate from minus 16 per cent to plus 7 per cent did not augment urine flow. Certain of the following observations suggest that the anticipated diuretic response did not occur because the

FIG 1 High-power view of ablated thyroid

patient was on a restricted salt intake. The postoperative nitrogen figures indicate increased protein storage.

As stated above, it has not been possible to decide whether the stimulating effect of thyroid upon water excretion is simply one expression of a general increase in metabolic processes or whether it is due to some more specific mechanism. Believing that information bearing on this point might be obtained by raising the postoperative basal metabolic rate to its former level with thyroid and again with some dissimilar agent under conditions which should permit maximum urine flow, the patient was placed on a generous salt intake and first given enough dinitrophenol to elevate the metabolic rate to about the preoperative level. Chart 2 shows the daily urine output and nitrogen balance under these circumstances and under subsequent thyroid administration. Dinitrophenol for five days promptly raised the basal metabolic rate to

CHART 1 The columns in each period are the averages for the number of days indicated below

■ —24 hour urine output
▨ —sodium chloride intake

■ —urine output
▨ —nitrogen intake
□ —nitrogen output

minus 10 per cent but no diuresis occurred, the nitrogen balance remained virtually unchanged and there was no appreciable loss of weight. After the metabolic rate had fallen the procedure was repeated with thyroid and, so long as the high salt diet was continued, there was an unmistakable increase in urine volume, withdrawal of extra salt diminished this diuresis despite continuance of thyroid but did not abolish it. The nitrogen balance became strongly negative, plasma cholesterol dropped and the patient lost weight rapidly. These findings confirm the statement⁵⁶ that the rate of protein oxidation is not increased by dinitrophenol and indicate that the diuretic activity of thyroid is not wholly explained by the general increase in tissue metabolism. Heinbecker and White¹⁵ in one dog in which thyroidectomy had diminished a chronic polyuria produced by hypothalamic puncture, also found urine flow increased by thyroid feeding but not by dinitroresol.

CHART 3 Effect of salyrgan on chloride excretion in diabetes insipidus

Chart 3 shows that the chloride output may be increased by salyrgan in diabetes insipidus as in normals, a point of some interest in view of the emphasis placed by some⁵² upon the constant hypotonicity of the urine in diabetes insipidus as an etiological factor. This observation was made preoperatively.

It may be incidentally remarked that in the preoperative period also we were unable to effect a greater reduction in urine volume by the combined use of pitressin and 1.8 gm of amidopyrine daily than by pitressin alone. Postoperatively the patient was given 100,000 international units of Progyron-B daily for one week in a theoretical attempt to produce oliguria by inhibition of the anterior pituitary, but without demonstrable result.

By December 1936, four months after thyroidectomy, a definite hypochromic anemia had developed: erythrocytes 4,460,000, hemoglobin 78 per cent, leukocytes 10,200, eosinophiles 3 per cent, basophiles, myelocytes and juveniles 0, stabs 7 per

cent, segmented 53 per cent, lymphocytes 30 per cent, monocytes 7 per cent. The electrocardiogram indicated progressive myocardial damage but the characteristic changes of myxedema had not developed. The patient's general appearance and behavior had not changed and it is only fair to state that he regarded himself as definitely improved by the operation. The non-protein nitrogen of the blood had not departed significantly from its normal preoperative level.

COMMENT

This report is not intended as a rigidly controlled experiment in human physiology. Obviously no guarantee can be made that all thyroid tissue was removed although the drop in basal metabolic rate and the rise in blood cholesterol indicates that the operation was as thoroughly performed as could be expected. It is poor therapeutics to substitute one disease for another and we are not inclined to repeat the procedure. The patient's subjective satisfaction, his increased response to pitressin and his ability to tolerate larger quantities of salt without commensurate polyuria suggest that the operation might be of some benefit to pitressin-resistant individuals in view of the theoretical possibility that this type is due rather to overactivity of the anterior pituitary than to hypopitressinemia.

In the absence of microscopic proof of absent thyroid tissue we cannot, however, claim that thyroidectomy in humans is less effective in reducing the polyuria of diabetes insipidus than it is in the experimental disorder of cats and dogs. That the thyroid exerts an appreciable effect on water exchange has been demonstrated and it is believed that this comes about either through its ability to sensitize the organism to a specific diuretic principle from the anterior pituitary or through a specific diuretic activity of its own.

SUMMARY

1 Current views regarding the etiology of diabetes insipidus are presented and the secondary rôle of thyroid activity assessed.

2 The changes in water, sodium chloride and nitrogen metabolism induced by total thyroidectomy in a human with diabetes insipidus are described. Although ablation of the thyroid was no more effective in reducing urine output than a low salt diet it definitely increased the patient's reactivity to pitressin and diminished his diuretic response to sodium chloride.

3 Comparison of the urine volume response to dinitrophenol and to desiccated thyroid suggests that the diuretic activity of thyroid is not due solely to its ability to elevate the metabolic rate.

4 Under the influence of salyrgan the kidneys of an individual with diabetes insipidus eliminated urine rich in chloride. Therefore, if diabetes insipidus is primarily due to inability of the kidneys to concentrate urine, the defect is not irreversible.

ADDENDUM

Since this was written several pertinent papers have appeared. Keller and Hamilton⁵⁷ oppose the Ranson school in reporting that complete denervation of the

posterior pituitary of cats does not always result in diabetes insipidus, they evidently place more emphasis upon their negative results than upon their successes. Keller⁵⁸ induced chronic polyuria in a dog by hypothalamic puncture, abolished it by hypophysectomy, and then reestablished it first by anterior lobe injections and again by thyroid feeding. He too feels that anterior lobe is necessary for the existence of diabetes insipidus but apparently believes that the diuretic and thyrotropic hormones are identical. McConnell⁵⁹ has reported striking amelioration of diabetes insipidus in a woman by removal of a thyroid adenoma, the fact that her polyuria was said to be uninfluenced by pituitrin in any form intensifies our desire to repeat these observations on pitressin-resistant individuals. Cutler's results from thyroidectomy were apparently not striking.⁶⁰

SUBACUTE BACTERIAL ENDOCARDITIS ACTIVE CASES WITHOUT BACTEREMIA *

By CHESTER S. KEEFER, F A C P, *Boston, Massachusetts*

FOR several years I have been interested in the group of patients with active bacterial endocarditis without bacteremia during life. These cases are not infrequent, and since organisms can be isolated from the vegetations post mortem, it is a matter of some interest to gather more information regarding the nature of the local lesion in the valves and the mechanism concerned with the absence of bacteremia.

The relative incidence of these so-called "bacteria free" [†] cases varies in the experience of different observers. In the last 54 cases of endocarditis which came to necropsy at the Boston City Hospital, [‡] the blood cultures and the heart's blood cultures at postmortem examination were negative in 13 or 24 per cent of the cases. In all of these the organisms were cultured from the vegetations and found by microscopic examination of the heart valves. Other observers report that in anywhere from 15 to 25 per cent of the cases which are observed, bacteremia cannot be shown to be present.

At this time, I present a summary of 15 cases which I have observed during life and at post mortem, including the clinical features, the histologic picture of the valves, and some observations regarding the bactericidal activity of the blood in patients with bacterial endocarditis.

ANALYSIS OF CASES

Of the 15 cases, all showed fever at some time during the course of the disease which lasted from six weeks to 12 months. Ten of the patients were between 21 and 40 years of age, one was under 20, and four were between 41 and 50 years. Seven gave a history of previous attacks of rheumatic fever occurring from one to 36 years before the onset of symptoms suggesting bacterial endocarditis. In two, there were congenital bicuspid aortic valves. All of the patients had heart murmurs. The aortic valve was involved alone in seven instances, and in combination with a mitral valvular defect in three. The mitral valve was involved alone in two cases, and the tricuspid alone in three. All of the individuals had an anemia.

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard Medical School, Boston.

[†] The term "bacteria free" cases was first introduced by Libman.² Sometimes it refers to cases without bacteremia but with organisms in the heart valves. In other instances, the term has been further restricted to those cases in which one can not obtain bacteria from the heart valves at necropsy (healing or healed bacterial endocarditis).

[‡] I am indebted to Dr. Parker, Director of the Mallory Institute of Pathology, for allowing me to use the records for this information. He has also been very generous in studying the sections of the heart valves with me.

Emboli were present in the lungs in all of the cases with right-sided valvular defects. The brain, spleen, kidneys, and extremities were the favorite sites for emboli in the peripheral circulation. A mycotic aneurysm of the superior mesenteric artery was found in one case and small infarcts of the intestine with melena in two. The heart's blood culture was negative at post mortem in all, except two that showed a terminal invasion by bacteria: one a Friedlander bacillus sepsis, the other a hemolytic streptococcus sepsis. In all cases organisms were cultured from the heart valves.

For purposes of discussion it is convenient to divide the cases into groups according to their outstanding clinical features during the course of the disease. I have separated the present cases into those with (1) right-sided heart lesions and multiple pulmonary infarcts, (2) symptoms and signs of progressive renal insufficiency, (3) progressive heart failure, (4) hemiplegia, as the outstanding feature, (5) splenomegaly and anemia. The salient features are presented in table 1.

Cases with Right-Sided Valvular Lesions The only conspicuous features of these cases which were not present in the others were the signs of multiple pulmonary infarcts and jaundice. Embolism in the general circulation was lacking but acute diffuse (non-embolic) nephritis was present in all. It has been pointed out in the past by Blumgart³ and others that right-sided bacterial endocarditis may be associated with multiple pulmonary infarcts without bacteremia, and it has been postulated that one of the reasons for the absence of bacteremia is due to the clearing capacity of the lungs. This is undoubtedly a factor but it can not be the only explanation since a number of patients with bacterial endocarditis and infections confined to the right side of the heart have bacteremia⁴. Of considerable interest in these cases is the presence of non-embolic nephritis, a feature of considerable importance in diagnosis. The splenomegaly that occurs is due to an acute splenic tumor, and the jaundice which usually appears late in the course of the disease is probably due to excessive blood destruction, chronic passive congestion of the liver, and the anoxemia following multiple pulmonary infarctions. The following case is an example.

Case 1 A young man, 34 years of age, entered the hospital complaining of cough and frequent attacks of vomiting. His past and family histories were negative. He had always been well until three months ago, when he noticed shortness of breath and paroxysmal attacks of coughing with some blood-streaked expectoration. There was, in addition, some aching pain in the chest, exaggerated by respiratory effort though it was more or less continuous. There was also dull, aching precordial pain and frequent attacks of sweating at night. Three weeks before admission all of his symptoms became exaggerated and his feet began to swell. It became necessary for him to go to bed, and he had remained there for three weeks before he came to the hospital.

Physical examination showed a thin, undernourished young man. His temperature was 102° F, pulse and respiratory rates were 120 and 40 per minute, respectively. The blood pressure was 150 mm of Hg systolic and 70 mm of Hg diastolic. There was moderate dyspnea but no orthopnea. The positive findings included Signs of

TABLE I
Summary of 15 Cases of Bacterial Endocarditis Without Bacteremia

| Case No., Age and Sex | Previous Rheumatic History | Signs of Infection | Signs of Valvular Disease | Embolic Phenomena | Heart Failure | Renal Disease | Blood Findings | Duration of Illness | Necropsy Findings | Miscellaneous Features |
|---|----------------------------------|-----------------------------|---|--|--|--|--|---------------------|--|---|
| Patients with Right Sided Valvular Lesions | | | | | | | | | | |
| 1 29 yrs ♀ | None | Chills and fever 101-101° F | Systolic murmur over lower end of sternum | Signs of multiple pulmonary infarcts. Rales and pleural friction rub where none elsewhere. | Slight peripheral edema and hepatomegaly | None B P 12/80 mm Hg | R B C 3 600 000-2 500 000 per cu mm Hgb 57-35% W B C 5 600-13 600 per cu mm | 6 weeks | Ulcerative endocarditis. Multiple pulmonary infarcts. <i>Streptococcus viridans</i> from heart valves. No signs of previous valve disease | Jaundice Infection followed an abortion 6 blood cultures during life were negative |
| 2 34 yrs ♂ | None | 101-103 F | Systolic and diastolic murmur over lower end of sternum | Signs of pulmonary infarction. Cough. Hemoptysis. Cyanosis. None else where. | Enlarged liver. Dyspnea. Slight peripheral edema | Urine showed red blood cells exists albumin B P 113/70 mm. Hg | R B C 2 922 000 per cu mm W B C 32 400 per cu mm. | 3 months | Acute endocarditis, tricuspid valves (<i>Staphylococcus aureus</i>) Septic embolus in pulmonary artery—infarcts left lung—serofibrinous pleurisy. Acute glomerulonephritis. Ascites Hydropneumothorax. | Jaundice 3 blood cultures during life were negative |
| 3 33 yrs ♂ | Pains in joints at age of 14 yrs | 99-100.4° F | Systolic murmur at lower end of sternum | Signs of pulmonary infarction in cough with pleurisy and pleurisy | Dyspnea. Dependent edema | Urine showed albumin, red blood cells, casts and leukocytes. Sp Gr 1.016 B P 180/100 mm Hg. Phthalen 20% 2 hrs CO ₂ 28 vol. % N P N 48.8-96.8 mg per 100 cc | R B C 2 636 000 per cu mm Hgb 42% | 4 months | Tricuspid endocarditis (<i>Streptococcus viridans</i>) Chronic passive congestion of liver Pulmonary infarct with emphysema. Chronic glomerulonephritis. Terminal <i>B. Friedländer</i> bacteremia | Blood cultures negative until day before death then <i>B. Friedländer</i> . Parovaginal ureteral fibrillation. Death from renal insufficiency |
| Patients with Symptoms and Signs of Renal Insufficiency | | | | | | | | | | |
| 4. 48 yrs ♂ | None | No fever | Aortic insufficiency | None | Edema of legs. Dyspnea | Urine showed albumin, red blood cells, white blood cells, casts. Sp Gr 1.012 N P N 105 mg per 100 cc B P 120/100 mm Hg. | R B C 3 350 000 per cu mm Hgb 52% W B C 16 800 per cu mm | 1 year | Vegetative endocarditis congenital tricuspid valve (<i>Streptococcus viridans</i>) Focal embolic nephritis | Beuscipid aortic valve. Course characterized by progressive nephritis and heart failure |
| 5 40 yrs ♂ | None | 98-101° F | Aortic insufficiency | Infarcts in spleen and kidneys | Edema of legs. Dyspnea | Urine showed albumin, red blood cells, casts. Sp Gr 1.016 N P N 30-106 mg per 100 cc B P 150/60 mm Hg | R B C 3 870 000 per cu mm Hgb 60% W B C 11 000 to 15 000 per cu mm | 6 months | Vegetative endocarditis aortic valve. Infarcts of spleen and kidneys. Chronic diffuse glomerulonephritis | Clabbed fingers 5 blood cultures negative Splenomegaly |
| 6 45 yrs ♂ | None | 99-100.5° F | Systolic and diastolic murmur at apex and base | None | Edema of extremities | Urine showed albumin, red blood cells, rare casts. Sp Gr 1.011-1.017 Phthalen 52% 2 hrs B P 165/80 mm Hg N P N 50 mg per 100 cc | R B C 3 440 000 to 2 125 000 per cu mm W B C 10 000 to 13 000 per cu mm | 1 year | Vegetative endocarditis, aortic valve and mitral valves (<i>Streptococcus viridans</i>) Healed infarcts in kidney and spleen. Chronic diffuse nephritis | |
| 7 30 yrs ♂ | 8 years ago | No fever | Systolic murmur at apex | Infarct of intestine | Generalized edema | Urine showed albumin, red blood cells, casts. Sp Gr 1.011 B P 160/100 mm Hg N P N 80 mg per 100 cc CO ₂ 21 vol % | R B C 2 392 000 per cu mm W B C 15 200 per cu mm Hgb 35% | 8 months | Vegetative endocarditis mitral valve and wall of aorta (<i>Streptococcus viridans</i>) Chronic diffuse nephritis. Infarct of jejunum | Splenomegaly Melena Diffuse petechial hemorrhages in skin |

solidification of the lung over the right lower lobe and a fibrinous pleurisy, moderate distention of the abdomen, an enlarged liver, and edema of the legs. The heart was moderately enlarged and there was a to-and-fro murmur over the precordium with systolic accentuation, which was best heard over the tricuspid area. The murmur was well localized and was not transmitted to the axilla.

Laboratory examination showed a red blood cell count of 2,952,000 per cubic millimeter, hemoglobin of 58 per cent, and a white blood count of 32,400 per cubic millimeter. Blood Wassermann was negative. The urine showed albumin and a moderate number of casts and red blood cells. The blood culture on admission was negative. There was no clubbing of the fingers.

The course of his illness was characterized by irregular fever, varying from 100° to 103° F. The pulse rate varied from 100 to 130, and the respiratory rate from 28 to 36 per minute. The spleen was not palpable. There were no petechial hemorrhages observed and no signs of peripheral embolism to the extremities. Four blood cultures during the course of a month were all negative. He continued to complain of recurrent attacks of pain in the chest, and signs of fluid appeared in both pleural cavities. Cyanosis became a feature of the illness. Finally, four days before death, the skin and sclerae had a definite icteric tint and the urine contained bile pigment. He failed gradually and died one month after admission, the total duration of the illness from the onset of symptoms being four months.

The necropsy showed endocarditis of the tricuspid valves, septic emboli in the pulmonary artery, with infarcts in the lung, sero-fibrinous pleurisy, acute diffuse glomerulonephritis, and a small encapsulated empyema between the lobes of the right lung. There was a moderate hydropericardium and ascites.

In short, then, this was a young man who had the symptoms and signs of an acute infection with fever, tachycardia, increased respiratory rate, signs of myocardial insufficiency, an enlarged liver, edema of the extremities, a systolic murmur over the precordium, a friction rub over the lungs, hematuria, jaundice, repeated negative blood cultures, and a progressive anemia with leukocytosis. The clinical features of the case suggested a right-sided valvular disease with multiple pulmonary infarcts and an acute, diffuse glomerulonephritis.

To sum up, in these cases the symptoms and signs of infection, the signs of right-sided valvular disease (tricuspid or pulmonary insufficiency), multiple pulmonary infarcts without signs of emboli in the greater circulation, with or without the signs of nephritis, and the late appearance of jaundice are the outstanding clinical features. Hemoptysis may be a feature in these patients and results from either pulmonary infarcts or mycotic aneurysms of the pulmonary vessels. These characteristics are highly suggestive of a bacterial infection localized on the right side of the heart.

Cases with Renal Insufficiency One of the most frequent signs of bacterial endocarditis with bacteremia is a focal embolic glomerulonephritis. In most instances, there are indications from the examination of the urine, such as hematuria, which suggest embolic lesions. In a few cases with bacteremia, the renal damage is so great that definite signs of renal insufficiency command attention, and one may find nitrogen retention, acidosis, and moderate hypertension.

In some of the cases with negative blood cultures during life and active lesions in the endocardium from which bacteria can be isolated, progressive renal insufficiency is a conspicuous feature. In the present group, focal embolic lesions were found in eight cases, and in the remaining seven the process was that of a diffuse glomerulonephritis.

In seven cases there were conspicuous signs of renal insufficiency as manifested by albuminuria, hematuria, loss of concentrating power, nitrogen retention, acidosis, and moderate hypertension. The most important features of these cases are the signs of progressive renal failure in an individual with valvular heart disease, with the symptoms and signs of a chronic infection and embolic phenomenon. The following case is an example.

Case 2 A 45 year old man complained of swelling of the face and feet. His family and past histories were negative. He stated that he had always been quite well until one month before admission to the hospital when he began to notice shortness of breath on slight exertion. His shoes became tight, especially at night, and his face and scrotum were swollen. In addition, he noted that his urine was somewhat cloudy and dark red in color. He became increasingly thirsty and passed more urine than formerly. His sleep was disturbed on account of nocturia. He had been in bed for one week before admission to the hospital. He had lost weight and his appetite had become progressively less.

Physical examination showed a well nourished and developed man who was alert and cooperative. His temperature was 101° F, pulse rate 80 per minute, and respirations varied between 20 and 25 per minute. The heart was enlarged to the left, measuring 14 cm. in the sixth interspace and extending 3 cm. to the right of the midsternal line in the fourth interspace. There was a harsh systolic murmur at the apex and base, and a soft blowing diastolic murmur in the aortic area. Lungs were clear. Blood pressure was 165 mm. of Hg systolic and 80 mm. of Hg diastolic. The abdomen was negative and there was slight edema of the ankles.

Laboratory examination showed a red blood count of 3,440,000 per cubic millimeter, hemoglobin of 55 per cent, and a white blood count of 14,800 per cubic millimeter. Specific gravity of the urine varied from 1.011 to 1.017. There was a slight trace of albumin, rare red blood cells and white blood cells, and no casts. Phenolsulphonphthalein excretion was 42 per cent in 2 hours.

After a period of several months in the hospital he improved, as far as his edema and symptoms were concerned, but the albuminuria persisted. The red blood cells had disappeared from the urine. He was discharged and returned six months later, complaining of increasing edema, slight dyspnea, nocturia, and loss of weight.

Physical examination at that time showed that he was dyspneic and cyanotic. He had râles at both lung bases and signs of aortic and mitral regurgitation. The liver was moderately enlarged and there was tenderness over it. There was extensive edema of the legs and scrotum.

Laboratory examination showed that the specific gravity of the urine varied from 1.010 to 1.015. Urine contained large amounts of albumin, many hyaline and granular casts, and a few red blood cells and white blood cells. The red blood cell count was 2,940,000 per cubic millimeter, the white blood cell count was 13,000 with a differential count of 75 per cent polymorphonuclears. Electrocardiographic examination indicated nothing abnormal. Blood pressure was 125 mm. of Hg systolic and 52 mm. of Hg diastolic. Temperature ranged between 99° and 100.5°. Non-protein nitrogen was 50 mg. per 100 c.c., gradually increasing to 65 mg. per 100 c.c. Phenolsulphonphthalein excretion was 5 per cent in two hours. Nitrogen retention, progressive anemia, and death followed 10 months after the onset of symptoms.

Necropsy showed Vegetations on the mitral and aortic valves. Heart's blood culture was negative. Streptococci of the viridans type were cultured from the heart valve. There was acute and chronic glomerulonephritis and a few focal embolic lesions, but the conspicuous feature was diffuse glomerulonephritis without embolization.

In summary, then, this man had the symptoms and signs of cardiac and renal insufficiency, with valvular heart disease, low-grade fever, negative blood cultures, and a progressive nephritis, death occurring with renal insufficiency.

Comment The renal lesions that are encountered in bacterial endocarditis have been studied especially in this country by Baehr and his associates^{5,6}. From Baehr's most recent study a number of important facts emerged. In a series of 91 cases of subacute bacterial endocarditis with bacteremia, the kidneys showed embolic lesions in 84 and were normal in five. In two there was a diffuse glomerulonephritis, in one, it was acute and in the other the process was a chronic one. A terminal azotemia was present in six.

In the 57 patients in the "bacteria free" stage the situation was somewhat different. It is well at this point to say that Baehr defines the "bacteria free" cases as those showing persistently negative blood cultures during life and no bacteria in the vegetations at post mortem when they were examined. In these cases he found evidence of healed focal embolic lesions in 34 and glomerulonephritis in 19, or 33.3 per cent.

In short, then, Baehr points out that patients with bacteremia show focal embolic lesions very often and diffuse glomerulonephritis infrequently. In the "bacteria free" cases diffuse glomerulonephritis is more common and the focal glomerular lesions usually show signs of healing.

It is perhaps well worth noting and emphasizing, then, that diffuse glomerular nephritis appears to be a striking feature in the cases without bacteremia. Rich, Bumstead, and Frobisher⁷ have produced nephritis in animals with hemorrhage into the capsules and tubules by injecting bacteria-free filtrates of broth cultures of organisms derived from bacterial endocarditis. From numerous observations at necropsy and from their experimental work, they expressed the opinion that the circulating bacteria and their products were responsible for the nephritis of bacterial endocarditis rather than focal embolic lesions. To account for the varying frequency of glomerular nephritis in patients with subacute bacterial endocarditis, Rich, Bumstead and Frobisher offer the suggestion that the difference may be accounted for by variations in the strain of infecting organism. Baehr has likewise suggested that the presence of streptococci in the blood can not be the sole cause of the glomerular nephritis inasmuch as it is seen most often in cases without bacteremia. It was suggested that the glomerular nephritis was related to the phenomena concerned in or following the death of the bacteria. In brief, one group of investigators feels that differences in the infecting strain of bacteria are of importance, whereas others postulate differences in the immune mechanism of the disease in various indi-

viduals Whatever the final explanation may be, it is well to consider bacterial infection of the heart valves as a cause of glomerulonephritis, and it is also important to appreciate that it is most common in cases without bacteremia

Cases with Cardiac Insufficiency As a late phenomenon, many patients with active bacterial endocarditis and bacteremia develop all of the symptoms and signs of congestive heart failure In these, the symptoms and signs of infection invariably precede those of heart failure A few of the patients with negative blood cultures came under observation with the symptoms of cardiac insufficiency which dominated the illness from the beginning of symptoms The following case is an example

Case 3 A 48 year old man complained of palpitation and dyspnea of three months' duration He had had an attack of rheumatic fever at the age of 12 years but no symptoms referable to his heart and no pains in his joints until three months before admission At that time he began to notice dyspnea, palpitation, and slight edema of the extremities, especially at night On occasions, he had attacks of paroxysmal dyspnea which would awaken him from sleep and cause him to gasp for breath For one month before admission he had had recurrent chills and fever, followed by sweating, progressive weakness, chronic cough, and some pain in the left upper quadrant radiating to his chest and abdomen His past history was essentially negative except for the attack of rheumatic fever Family history was inconsequential

Physical examination showed a poorly developed and nourished man with dyspnea and the appearance of being acutely ill His temperature was 99.5° F, pulse and respiratory rate were 100 and 22 per minute, respectively Blood pressure was 100 mm of Hg systolic and 48 mm of Hg diastolic Positive findings were Moderate enlargement of the heart to the left, a blowing systolic murmur at the apex, and a systolic and diastolic murmur at the aortic area There were râles at both lung bases The abdomen was moderately distended but no free fluid was detected There was slight edema of the extremities and moderate clubbing of the fingers

Laboratory examination showed that the specific gravity of the urine varied from 1.010 to 1.028 There were rare red blood cells and, on occasions, numerous casts The red blood cell count was 3,300,000 per cubic millimeter, hemoglobin 72 per cent, and the white blood cell count 3,500 to 8,600 per cubic millimeter The differential count was normal Sedimentation rate was increased Electrocardiographic examination showed a P-R interval of 0.16 sec and left ventricular preponderance Fluoroscopic examination of the heart showed a dilated pulmonary artery Blood culture was negative

The patient was observed for a period of three months During that time he had low-grade fever, ranging from 99.5° to 100° F He complained of pains in his joints which were controlled to some extent by the administration of sodium salicylate The edema which was present on admission gradually subsided but he continued to have râles in both lungs and attacks of paroxysmal dyspnea The spleen was not felt at any time On a few occasions a few petechial hemorrhages were observed on the lip, the buccal mucosa, and over the arms and chest The course of the patient's illness was one of progressive failure with the predominating symptoms those of cardiac insufficiency, such as dyspnea, restlessness, and moderate edema of the extremities There was a progressive anemia, the hemoglobin declining to 55 per cent, without any response to iron or liver extract therapy Eleven blood cultures taken over a period of three months of observation were all negative

At necropsy, the heart's blood culture was negative The anatomical diagnoses were Healed rheumatic aortic endocarditis, vegetative endocarditis of the aortic

valves. Culture of these vegetations revealed *Streptococcus viridans*. There was chronic passive congestion of the liver and spleen, a few infarcts in the spleen, and a few focal embolic lesions in the kidney.

In brief, then, a patient who had had rheumatic fever at the age of 12 years, develops the symptoms of cardiac insufficiency six months before death. The clinical course during the last three months of his life was characterized by progressive cardiac insufficiency, the signs of a low-grade infection (slight fever, loss of weight, and a progressive anemia), aortic insufficiency, clubbed fingers, petechial hemorrhages in the skin, and persistently negative blood cultures, death resulting from cardiac insufficiency. The heart at postmortem examination showed vegetative endocarditis of the aortic valves from which *Streptococcus viridans* were isolated. The section of heart valve is shown in figure 1.

FIG 1 Vegetation on aortic valve. The deeply staining material at the periphery of the valve is a mass of bacteria.

There were two cases in which hemiplegia was the first indication of bacterial endocarditis, and a third in which splenomegaly was an outstanding feature. They have been summarized in the table.

DIFFERENTIAL DIAGNOSIS

The conditions which are likely to be confused with infective endocarditis without bacteremia are active and progressive rheumatic infections and the cases of non-bacterial thrombotic endocarditis^{8, 9, 10}. The absence of embolic phenomena, splenomegaly, and nephritis and the presence of electrocardiographic changes and pericarditis favors the diagnosis of rheumatic fever. The history of rheumatic fever and a positive nucleoprotein skin reaction is also of assistance.

The cases of non-bacterial thrombotic endocarditis may give rise to greater difficulty in that they may show clinical features which are common to either rheumatic fever or infective endocarditis, in that they may have pericarditis, polyserositis, nephritis, and skin eruptions of lupus erythematosus, but no electrocardiographic changes. Thrombopenic purpura, hemorhagica and deforming arthritis may be features. All these features, together with the course of the disease, are helpful in the diagnosis.

LESIONS IN THE HEART VALVES

In view of the observation that the blood remained sterile in these cases it was of some interest to study the heart valves and vegetations from which organisms were grown at post mortem and compare the finding with cases showing bacteremia.

Histologic Changes in Heart Valves When the sections from the heart valves showing vegetations were studied with the microscope for purposes of comparing the lesions in the cases without bacteremia with those with bacteremia, it was found that it was impossible to distinguish the cases on this basis. Some of the vegetations showed organization and fibrosis, others from the same valve would exhibit no signs of healing. Morphologically, the organisms appeared to be the same although careful studies for differences in their growth characteristics were not investigated.

The sequence of events in the development and advance of the lesions seems to be somewhat as follows. There is an injury or damage to the endothelium of the valvular surface, which is followed by the formation of platelet and fibrinous thrombi, proliferation of the fibroblasts, and endothelial cells. The infecting vegetations are usually superficial, covering the surface of the valve and consisting of masses of fibrin and platelets. The organisms frequently collect and arrange themselves along the border of the vegetations, and beneath them in some cases one sometimes sees masses of leukocytes. In other vegetations it can be seen that the dense clumps of bacteria at the periphery of the thickened layer of fibroblasts are surrounded by a wall of leukocytes and fibrin.

When the vegetations organize, one finds a gradual transformation of the fibroblastic layer into dense connective tissue. The vegetations themselves are covered with dense fibrin and deeply stained material and it appears as

if the vegetations were being completely surrounded by fibrous tissue, and shut off from the circulating blood

The histologic findings in these cases are in accord with those described by Wright ¹ who could find no difference in the vegetations from cases with and without bacteremia

It does not seem that one can account for the absence of bacteremia in these cases solely on a basis of the difference in the anatomic structure of the vegetations on the heart valves. While it can not be proved at present, there is suggestive evidence from animal experimentation that the cases with negative blood cultures probably have a sufficiently high bactericidal power of the blood to maintain the clearing mechanism at a high level of efficiency. The other possibility is that the organisms are growing so slowly that they can be removed as fast as they enter the circulating blood. That they enter the circulating blood from the vegetations is supported by the fact that patients with negative blood cultures often have emboli in the various organs which contain bacteria

COMMENT

It can not be said that the cases without bacteremia differ essentially from those with bacteremia during life, insofar as their clinical features and course are concerned. The total duration of the illness may be the same in both groups, and there may be no distinguishing marks by which they can be separated during life. There is possibly one exception which is noticeable, and that is the incidence of renal insufficiency in the cases without bacteremia. This question has been discussed above and need not be repeated here. No one will deny, however, that renal failure may be observed in cases with bacteremia even though it seems to be less common than in those without bacteremia during life.

Inasmuch as there is difficulty in distinguishing these two groups of patients on a basis of the clinical features and course of the disease, it will be well to review a number of the salient features and facts regarding the pathogenesis of bacterial endocarditis in man and in the experimental animal. In this way, we seek an explanation for the cases under discussion.

THE PATHOGENESIS OF BACTERIAL ENDOCARDITIS IN MAN

In reviewing the conditions in which subacute bacterial endocarditis is seen in man, certain points stand out. First of all, it is generally conceded that it is most commonly observed in individuals who have damaged valves resulting from a previous attack of rheumatic fever or from congenital valvular defects. It is rare when the preceding rheumatic infection has been an attack of chorea ¹¹. In particular, it seems to be especially common in patients who have chronic valvular heart disease and a regular rhythm, of these, the ones who seem to be most vulnerable are those who are in fairly good health, comparatively free from dyspnea and who fail to give a history

of recurrent attacks of rheumatic fever. Patients with aortic regurgitation alone or in combination with mitral valvular disease seem to develop the disease more often than those with distinct signs of mitral stenosis. It is exceedingly rare in syphilitic aortic insufficiency, in individuals without previous cardiac murmurs, and in patients with hypertension. It is practically unknown in patients with a history of previous attacks of heart failure or established auricular fibrillation and, to my knowledge, it has been reported as following a coronary occlusion in only one case¹²

Of the congenital defects, the commonest predisposing lesion seems to be congenital bicuspid aortic valves, and a patent ductus arteriosus. In table 2 I have summarized the various conditions in which it has been observed.

TABLE II

Conditions in Which Bacterial Endocarditis Has Been Observed in Man

- 1 Rheumatic Heart Disease—acute or chronic
 - a* Aortic regurgitation
 - b* Aortic regurgitation with mitral insufficiency
 - c* Mitral stenosis
 - d* Tricuspid insufficiency
- 2 Congenital Heart Disease
 - a* Bicuspid aortic valves
 - b* Patent ductus arteriosus
 - c* Coarctation of aorta
 - d* Subaortic stenosis
 - e* Patent interventricular septum
 - f* Pulmonary stenosis
- 3 Coronary Occlusion
- 4 Thrombotic Endocarditis (Chronic disease)

In short, it can be said that the patients who are likely to develop bacterial endocarditis are those with rheumatic or congenital valvular defects, in a good state of health, with a normal cardiac rhythm. It is not likely to develop in an individual with hypertension, or a normal heart, or in anyone with auricular fibrillation, or in a patient who has had previous attack of congestive heart failure.

In addition to the above factors there are other considerations in the pathogenesis of subacute bacterial endocarditis which require comment, namely, what are the factors predisposing damaged heart valves to infection by bacteria? what is the portal of entry? and why do the organisms localize?

The first question has been discussed and investigated by a number of observers. There have been two main views, namely, that the heart valves are infected by bacterial emboli focalizing in the valves, and that the organisms invade the valves from the outside. That is to say, it is an infection of the surface of the valve.

The chief argument against intravascular emboli being the sole cause of infection of the heart valves is the fact that it is not possible to demonstrate blood vessels in the heart valves of all individuals. On the other hand, it can be shown that bacterial infection of heart valves is most often superficial and the bacteria occur at the periphery of the thrombi on the valves.

Leary,¹³ Mallory and I¹⁴ have demonstrated bacteria in the very early lesions of bacterial infection of the heart valves and endocardium, and the organisms seem to invade the valves from the surface. How then do microorganisms gain a foothold on an injured valve? It is the opinion of Pappenheimer and Von Glahn¹⁵ that most cases of subacute bacterial endocarditis are due to an infection of rheumatic vegetations by microorganisms, and Grant, Wood and Jones¹⁶ have brought forth convincing evidence that platelet thrombi are exceedingly common on damaged or injured valves, and these thrombi serve as peculiarly favorable areas for the localization of bacteria. They found in studying non-bacterial thrombotic endocarditis that these thrombi occurred on valves which were thickened and on the ones in which infective endocarditis is likely to develop. Moreover, Grant has demonstrated platelet thrombi on heart valves which had been experimentally damaged, showing that injury to a heart valve is followed by the deposition of a platelet thrombus. It is now known that non-bacterial thrombotic endocarditis occurs in a variety of conditions⁸ and, in studying this condition further, I have found that these thrombi may become infected and produce a bacterial endocarditis. Table 3 summarizes the conditions in which I have observed non-infected thrombotic endocarditis and the cases in which such thrombi have become infected by bacteria.

TABLE III
Summary of the Conditions in Which Non-Infected and Infected Thrombotic Endocarditis Are Observed

| <i>Non-infected</i> | | <i>Infected</i> | |
|------------------------|---|-------------------------------|---|
| Chronic heart disease | 3 | Chronic heart disease | 2 |
| Leukemia | 1 | Leukemia | 2 |
| Appendix abscess | 1 | Carcinoma | |
| Pulmonary tuberculosis | 2 | Cervix | 1 |
| | | Lung | 2 |
| | | Stomach | 1 |
| | | Hypernephroma | 1 |
| | | Cirrhosis of liver | 1 |
| | | Stone in the common bile duct | 1 |

It seems clear that either thrombotic or rheumatic endocarditis may serve as a suitable area for bacteria to localize and gain a foothold, and since these thrombi are relatively free from leukocytes, microorganisms are destroyed with difficulty and are able to survive. Since bacterial endocarditis occurs very often in conditions which favor the development of thrombi on the valve leaflets (damaged valves, acute rheumatic and chronic diseases) it is not far-fetched to believe that these thrombi are an important predisposing factor in the pathogenesis of bacterial endocarditis.

I should not like to leave the impression that it is always necessary to have a previously damaged valve in order for bacteria to gain a foothold on the heart valves and thrive. Indeed, it is well recognized that some microorganisms focalize on previously normal heart valves, and it is highly possible, as suggested by Wadsworth, that acute injury to the heart valves by bacteria serves as an excellent predisposing factor for the localization of

infection It is well worth recalling, however, that the majority of cases of *Streptococcus viridans* endocarditis occur in patients with previously damaged valves, and this must be taken into account in any discussion of the pathogenesis of the disease

The question now arises regarding the circumstances that permit bacteremia and the portal of entry for the infecting organism? It is well recognized that it is often impossible to tell when the original invasion of bacteria took place, since the disease begins in most instances in an insidious manner and is not preceded by any previous noticeable infection that would serve as a focus of entry Upon reflection, this does not seem at all curious since it would be surprising if green producing streptococci did not invade the circulating blood frequently since they are present in the mouth from a period shortly after birth and persist until death That they invade the circulating blood in a variety of diseases has been amply demonstrated by Lichtman and Gross,¹⁷ Epstein and Kugel,¹⁸ and Swift and Kinsella,¹⁹ and one knows that they often invade the blood following tonsillectomy and the extraction of teeth There are now on record a number of cases of subacute bacterial endocarditis in which the disease first asserted itself following the extraction of teeth or tonsillectomy, or respiratory infections, and one is also familiar with the cases that follow local areas of suppuration²⁰

In addition to the presence of thrombi on the heart valves and the bacteremia, it is necessary to account for the localization of bacteria It is a general rule in bacterial infections that the localization of bacteria in tissues is consistent only in the cases in which there are antibodies present It has been demonstrated by Kinsella,²¹ Wright,²² Miller and Branch,²³ Libman,²⁴ and Swift²⁵ that the blood from patients with active infections and bacteremia shows agglutinins for the homologous organism and is actively bactericidal Spink and I²⁶ have demonstrated that the blood from bacteremic cases is not only capable of killing the organisms which are present in the circulating blood but is often capable of killing many thousands of microbes which are added to it Furthermore, and this we consider of significance, the blood of some normal individuals is highly bactericidal for most strains of *Streptococcus viridans* which have been isolated from cases of proved bacterial endocarditis

To sum up the information regarding the pathogenesis of subacute bacterial endocarditis in man it would appear that a damaged heart valve, the presence of platelet thrombi, transient bacteremia, and the presence of anti-bacterial antibodies which aid in the clearing of the blood stream and the localization of bacteria are all important in determining the development of bacterial endocarditis

EXPERIMENTAL BACTERIAL ENDOCARDITIS

Bacterial endocarditis has been produced experimentally in animals (rabbits,²⁷ dogs,²⁸ horses,²⁹ and chickens³⁰) by several methods and by different

investigators. These observations are of great importance in understanding some of the features of the infection in man.

The observations of Herrmann²³ in regard to endocarditis in dogs are significant. He found that the normal heart valves of dogs were relatively immune to infection by *Streptococcus viridans* when large doses of organisms were injected intravenously. When, however, the aortic valves were injured, a large number of puppies died from the results of a spontaneous streptococcus endocarditis. This was also noticeable in parturient bitches. In all, 20 per cent of his dogs with experimental aortic regurgitation developed spontaneous streptococcus endocarditis. Of further interest, however, it was found that dogs with damaged heart valves were found to be uniformly susceptible to bacterial implantations of streptococci when they were injected intravenously. Similar observations have been made in dogs by Kinsella²⁴. In addition, he found that it was easier to produce endocarditis in dogs when they had been partially immunized. Of considerable interest in respect to the development of endocarditis on the damaged heart valves of dogs are the observations of Grant¹⁶ that platelet thrombi form on the heart valves shortly after they have been ruptured, and it is possible that they serve as foci for the localization of bacteria.

The same kind of experiments have been carried out in rabbits with somewhat similar results, with the exception of the fact that repeated injections of organisms into rabbits with normal heart valves are followed by endocarditis in a certain number of cases. Wright²² has shown that infection of the valves is more likely to occur in animals that have been treated with vaccines so that demonstrable antibodies are present in the circulating blood. It can be shown, however, that when the valves of a rabbit are damaged their resistance to infection is greatly lowered.

The observations of Wadsworth²⁵ on the occurrence of endocarditis in horses are of the highest significance to our understanding of the pathogenesis of bacterial endocarditis. He found that endocarditis developed very frequently in horses that had been immunized against pneumococci. The infection of the heart valves usually took place after the animal had a high antibody titer in the circulating blood and there was no convincing evidence that the infection took place early in the course of the injections. The blood cultures of these animals remained sterile and the organisms in the vegetations were few and could be cultured from the valves with difficulty, and were found in sections of the heart valves in only small numbers at post mortem.

In short, the findings in the horses studied by Wadsworth are similar in many respects to the "bacteria free" cases in man. That is to say, the endocarditis is active, the blood remains sterile. It is perhaps important to recall that endocarditis was produced in these animals without mechanical injury to the heart valves and it did not develop until there was a high antibody titer in the blood—a condition favoring the localization of bacteria.

To sum up this discussion, it may be said that infection of the heart valves is seen most often in animals following mechanical injury and the injection of microorganisms intravenously. Following mechanical injury to heart valves, platelet thrombi form and serve as a focus for the localization of bacteria, and while infection may occur spontaneously, it is most frequent following the injection of bacteria. Furthermore, when there is no previous injury to the valves, endocarditis develops more frequently following repeated injections of organisms into animals which develop active bactericidal antibodies. It would appear, then, that injury to the heart valves, the presence of antibodies, and bacteremia are all important and necessary in the pathogenesis of bacterial endocarditis. It is not at all unlikely in many instances, as suggested by Wadsworth, that the original injury to the valves is bacterial in origin since Leary and Mallory and I have demonstrated bacteria in very early lesions on the heart valves and endocardium.

IMMUNOLOGIC STUDIES IN BACTERIAL ENDOCARDITIS

The immune reactions that can be demonstrated in the circulating blood of patients with bacterial endocarditis have been studied by Kinsella,²¹ Wright,²² Miller and Branch,²³ Swift,²⁵ Libman,²⁴ and ourselves. Inasmuch as these studies have a direct bearing on the problem of the pathogenesis of bacterial endocarditis they are presented in detail. While Kinsella was unable to show that there was any constant identity between the various strains of streptococci isolated from cases of bacterial endocarditis, he demonstrated quite conclusively that the patient's blood serum contained agglutinins and complement fixing antibodies for homologous strains of organisms. Miller and Branch demonstrated homologous agglutinins in their case and Wright²² found that the blood of septicemic cases contained antibodies and was actively bactericidal. Moreover, in animals with bacterial endocarditis there was evidence of antibody production even in the face of an increasing septicemia. Wright considered the bacteremia in bacterial endocarditis to be a secondary phenomenon resulting from an escape of organisms from the lesions in the heart valves and thought that the bacteria increased in the blood stream of his animals because they multiplied in the lesion and were discharged faster than they could be removed. That this is true in man seems to be proved from the remarkable case of subacute *Streptococcus viridans* septicemia which was cured by excision of an arteriovenous aneurysm of the external iliac artery and vein, reported by Hamman and Rienhoff.³¹ In this case, the removal of the focus (vegetations in the aneurysm) was followed by a clearing of the blood stream and complete recovery. This case seems to prove beyond any doubt that the bacteremia in these cases is an overflow phenomenon. In common with Wright, I have found that the cases which are negative are always negative, and since numerous blood cultures were taken during life in all of the cases

reported herewith, it is unreasonable to suppose that faulty technic was responsible for our failure to isolate the organisms during life.

Within recent years it has been found by Howells and Corrigan,³² Levine,³³ Derrick and Fulton,³⁴ and Swift²⁵ that patients with subacute bacterial endocarditis fail to show skin reactions to filtrates of streptococci and we have confirmed these findings in 10 instances. This examination may be of significance in the diagnosis of obscure cases of bacterial endocarditis.

While it has not been proved in the human cases that the reason for the negative blood cultures during life is the presence of a high antibody titer

| Normal control | + | + | + | + | 0 | 0 | 0 | " |

of the blood there is suggestive evidence, from studies on animals and in particular from the studies by Wadsworth, that such is the case. An additional factor is the small numbers of organisms present in the vegetations.

Baehr suggests that some patients with bacterial endocarditis develop an immunity to the infecting organism which is of sufficient degree to kill off the bacteria shortly after the onset of the disease. In this way, he explains the bacteria-free cases. From numerous observations on man and animals it does not seem unreasonable to suppose that the reason for the negative blood cultures is due to the fact that the organisms are removed from the circulating blood as rapidly as they enter it. That they are present in the blood from time to time is attested by the presence of embolic phenomena in these cases. The reason they continue to live in the vegetations of the heart valves is probably due to the fact that the bacteria are situated in an area where there are relatively few leukocytes or tissue phagocytes and the bactericidal action can not operate effectively.

Studies on the bactericidal power of the whole blood of patients with bacterial endocarditis and bacteremia indicate that normal individuals are often able to kill large numbers of organisms that can be isolated from the blood of patients with endocarditis. Likewise, the patients with bacterial endocarditis can do the same. This is illustrated in table 4 and chart 1.

CHART 1 The temperature chart together with the various immune reactions that were followed in a patient with bacterial endocarditis

In short, then, it would appear that normal individuals as well as patients with bacterial endocarditis possess antibacterial antibodies against some strains of *Streptococcus viridans* derived from endocarditis. This is suggestive evidence of a defense mechanism for the clearing of the blood stream of bacteria, once they gain entrance to the circulation. While it is not known whether all of the patients who have immune bodies in their circulating blood at the time of an active infection have had antibodies before the onset of infection, it is suggested by our observations on some normal individuals, that this is possible, although Swift²⁵ records a case in which agglutinins against the homologous organism were not present before infection and appeared after its development. This is a question requiring further study.

SUMMARY AND CONCLUSIONS

A group of 15 cases of active bacterial endocarditis without bacteremia is described and summarized. For purposes of discussion they were divided into five groups: (1) those with right-sided valvular disease, multiple pulmonary infarcts, and jaundice, (2) patients with renal insufficiency, (3) patients with heart failure, (4) patients with splenomegaly and anemia, and (5) patients with hemiplegia.

All of the patients had physical signs of valvular disease. Non-syphilitic aortic regurgitation was present in ten. The mitral valve was involved alone in two and the tricuspid alone in three.

There was no essential difference in the clinical course of the patients with bacteremia and in those without bacteremia with the possible exception of the fact that the non-bacteremic cases were more apt to have renal insufficiency as an outstanding feature of their illness.

The pathogenesis of bacterial endocarditis as it is observed in man and the experimental animal was reviewed and it was pointed out that the following factors are significant: a previously damaged valve, the presence of platelet thrombi on the valves, a transient bacteremia and the presence of antibodies that encourage the localization of bacteria.

Bactericidal studies in the blood of patients with bacterial endocarditis were presented, and it was concluded that some normal individuals as well as patients with bacterial endocarditis have antibodies which are capable of killing organisms derived from cases of bacterial endocarditis.

From the foregoing discussion it seems reasonably plain that bacterial endocarditis can be produced in animals under the same circumstances as exist in man, namely, the presence of damaged valves, platelet thrombi on the valves, bacteremia, and the presence of antibodies. There also is highly suggestive evidence that the human cases with negative blood cultures have a condition analogous to the experimental endocarditis of horses as described by Wadsworth. This, however, requires further study and proof. In any event, it is well to recognize this group of cases since they aid in understanding the infection and should encourage one to look for ways of destroying organisms in the valves.

DISTURBANCES OF RATE AND RHYTHM IN ACUTE CORONARY ARTERY THROMBOSIS

By ARTHUR M MASTER, M D, F A C P, SIMON DACK, M D, and HARRY L JAFFE, M D, *New York, N Y*

INTRODUCTION

INVESTIGATORS¹⁻⁵ during the nineteenth century observed that ligation of the coronary arteries in animals very frequently produced cardiac arrhythmias either transient or severe enough to cause cardiac standstill, but their exact nature was not defined until the beginning of the present century. In 1909, Lewis⁶ reported that after ligation of the left coronary artery multiple premature beats were recorded by venous pulse and electrocardiographic tracings. These frequently formed paroxysms of ventricular tachycardia from which ventricular fibrillation sometimes developed. Subsequent workers⁷⁻¹² confirmed these observations. Recently, in addition, de Waart et al,¹¹ after tying off the right coronary artery found sinoauricular and auriculoventricular block. In all these observations it is noteworthy that auricular fibrillation and flutter were rarely encountered, and auricular and nodal tachycardia only occasionally.⁹

In man also, the majority of authors¹³⁻²¹ have noted the presence of arrhythmias in coronary artery thrombosis. While White²⁰ thinks they occur in only a small number of cases, Levine²² observed them in more than one-fourth of his series. The incidence of the significant arrhythmias, that is, those other than premature beats, in several large series²²⁻³¹ varies between 9 and 27 per cent, the average in over 800 cases being 17 per cent. As in animals, the most common irregularity is premature beats, usually ventricular, which occurred in about one-quarter of the cases. Next in order of frequency is auricular fibrillation. In the reports mentioned above its incidence was usually 6 to 7 per cent, although Levine's²² figures were as high as 23 per cent and Meakins and Eakin's²⁶ 14.5 per cent. Brill,³² too, observed that it frequently appeared early in coronary thrombosis.

The other arrhythmias auricular flutter, auricular and nodal tachycardia, ventricular tachycardia, nodal rhythm and heart block, in the experience of all authors²³⁻³¹ occurred in only a small percentage of cases. Auricular flutter was observed by Parkinson and Bedford²⁴ and Jervell²⁹ in 3 to 4 per cent of cases and by Howard²⁷ in only 0.6 per cent. However, of nine fatal cases of coronary artery thrombosis described by Longcope,³³ four had auricular flutter. Other authors^{28, 34, 35} also observed this ar-

rhythmia in coronary artery thrombosis. Similarly, auricular and nodal tachycardia occurred infrequently^{24, 28, 36, 37}. Sinoauricular block,^{29, 38} sinus bradycardia^{39, 40} and nodal rhythm^{38, 40, 41, 42} have been encountered but once or twice in any one series. The average incidence of heart block, partial and complete, is 2 to 5 per cent,²²⁻³¹ although Appelbaum and Nicolson³⁷ found three instances in 30 cases. Salcedo-Salgar and White,⁴³ in a recent study of heart block in more than 300 cases of coronary thrombosis, found the incidence to be 4.2 per cent, this figure included 10 cases of partial and only four of complete block. In marked contrast is the experience of Schwartz⁴⁴ who over a period of a few years observed 15 cases of complete heart block with Stokes-Adams syndrome precipitated by coronary thrombosis. In this connection may be mentioned the recent analysis by Graybiel and White⁴⁵ of 72 cases of complete heart block of which approximately 10 per cent followed an acute coronary thrombosis.

Because of the frequency of ventricular tachycardia in experimental coronary ligation⁶⁻¹² its importance in coronary artery thrombosis has been emphasized in numerous case reports in the literature^{8, 22, 42, 46-59}. It is significant, however, that most of the authors have reported one or only a few cases of coronary artery thrombosis with ventricular tachycardia, or rarely, a small series of ventricular tachycardia in which the chief etiological factor was recent or old myocardial infarction⁶⁰⁻⁶³. Analysis of large series of cases of coronary artery thrombosis, however, gives a truer perspective of the rarity of this arrhythmia. Although Levine⁶³ intimates that it occurs in approximately 5 per cent of cases, in 470 cases in the series mentioned above,²³⁻³¹ there were but three cases, an incidence of 0.6 per cent.

It has been found that not infrequently two or more arrhythmias occur simultaneously or in close association^{35, 38, 41, 42, 53, 57, 64, 65}. Hamman¹³ considered such a sequence diagnostic of coronary artery thrombosis.

MATERIAL

An analysis of the arrhythmias found in 300 cases of coronary artery thrombosis is presented in this report (table 1). Excluding premature beats, present in one-quarter of the cases, the incidence of arrhythmias was 14 per cent. Forty-two patients presented the following 46 irregularities:

| | | |
|---|----|---|
| Auricular fibrillation | 22 | |
| Auricular flutter | 3 | |
| Paroxysmal tachycardia | 9 | |
| auricular | | 3 |
| nodal | | 2 |
| ventricular | | 1 |
| undetermined | | 3 |
| Nodal rhythm | 3 | |
| Wandering pacemaker | 1 | |
| Heart block | 8 | |
| incomplete heart block with dropped beats | | 3 |
| complete A-V dissociation | | 3 |
| combination of both types | | 2 |

Prolongation of the P-R interval, which was very common, and bundle-branch block are not included in this paper as they will form the material of a future article. For the same reason A-V heart block will not be considered in great detail.

Significant differences were observed between patients with arrhythmias and those with regular rhythm (table 1). In the former group, the ratio of men to women was 23:1, in the latter 4:1, apparently women are more prone to develop irregularities than men. This applied particularly to auricular fibrillation and heart block. The average age was slightly higher in those with arrhythmias. Furthermore, hypertension and cardiac enlargement occurred in four-fifths of the cases with an arrhythmia, whereas in those without, hypertension was present in 65 per cent and cardiac enlargement in only 60 per cent. Heart failure also was more common when an arrhythmia existed, that is, in 85 per cent as compared to 70 per cent. It is obvious, then, that arrhythmias occurred in the more severely ill patients, a fact further supported by the high mortality rate in this group, 39 per cent as against only 22 per cent in the remainder of the series. The mortality rate for the entire series of 300 cases was 26 per cent. Most of the deaths were in the group with auricular fibrillation and complete heart block. That the arrhythmia may have been merely one expression of the severity of the attack and not the cause of death, however, is probable in view of the fact that half the patients died some time after the cessation of the arrhythmia.

Almost half the arrhythmias appeared during the first three days succeeding the attack and the majority during the first week. In some cases it followed immediately the onset of the attack. However, the arrhythmia may set in at any time, even in the third week. The duration of the arrhythmia was usually short. In over half the cases it lasted 24 hours or less, and in some only a few hours. Auricular fibrillation and paroxysmal tachycardias were as a rule, transitory, heart block and nodal rhythm usually persisted longer, occasionally several weeks.

It is interesting that the presence of previous occlusions did not increase the incidence of arrhythmias. This would indicate that the latter depend upon the acute changes in the heart.

PREMATURE BEATS

Premature beats occurring in 77 patients or one-quarter of the series was by far the most common irregularity encountered. They were ventricular in type in 46 cases, auricular and ventricular in 15, auricular alone in 14 and nodal in two. Multiple premature beats were found very frequently and in nine patients there was bigeminal or trigeminal rhythm (figures 7 and 9). The mortality rate in this group did not differ from the average for the entire series although it should be noted that when auricular or both auricular and ventricular premature beats occurred, the mortality rate was higher (35 to 40 per cent). But this finding might not hold true

TABLE I
Analysis of the Arrhythmias in 300 Cases of Coronary Artery Thrombosis

| | Total Control Series | Arrhythmias Excluding Premature Beats | Premature Beats | Auricular Fibrillation | Auricular Flutter | Nodal Rhythm | Paroxysmal Tachycardia | Complete Heart Block | Partial Heart Block |
|------------------------|----------------------|---------------------------------------|-----------------|------------------------|-------------------|--------------|------------------------|----------------------|---------------------|
| No of cases | 300 | 46 | 77 | 22 | 3 | 4 | 9 | 5 | 3 |
| Incidence | | 14.5% | 25.7% | 7.3% | 1.0% | 13.0% | 3.0% | 1.7% | 1.0% |
| Average age | 56 | 58 | 56 | 60 | 61 | 53 | 54 | 61 | 57 |
| Ratio—male female | 39 1 | 23 1 | 6 1 | 21 1 | 3 0 | 4 0 | 8 1 | 1 4 | 1 2 |
| Previous attack | 47.7% | 47.8% | 59.7% | 50.0% | 100% | 0 | 33.3% | 80.0% | 33.3% |
| Previous hypertension | 64.6% | 80.4% | 75.3% | 86.3% | 66.6% | 50.0% | 88.8% | 100% | 33.3% |

* Two to seven days' duration

in a larger series. Also the fact that the incidence of heart failure was practically the same as in the whole series is evidence that the clinical significance of premature beats is not important.

It has often been stated^{12, 66, 103} that the appearance of frequent ventricular premature beats may be the forerunner of ventricular tachycardia. Yet, this occurred only once in our series, when a fleeting paroxysm of ventricular tachycardia was observed during the course of a bigeminal rhythm (figure 9).

AURICULAR FIBRILLATION

Auricular fibrillation was found 22 times and occurred more frequently in women than in men. The average age of these patients was somewhat higher than in the general series. The incidence of increased arterial tension, enlarged heart and heart failure was definitely greater than in the control group and the mortality rate was high, 45 per cent. The latter was in large degree dependent on the heart failure since half the deaths occurred after the arrhythmia had spontaneously remitted. The average ventricular rate was 120–150 beats per minute (figures 1 and 2) which was undoubtedly associated with the high incidence of heart failure. Several cases, however, had a slow ventricular rate even without the use of digitalis.

The onset of auricular fibrillation usually occurred during the first few days and in two-thirds of the cases during the first week. It is significant that in 12, or more than half of the patients, its duration was 24 hours or less. In one instance it lasted two months and then ceased spontaneously, and in another it became permanent after digitalization. In five patients the irregularity was intermittent, alternating with periods of sinus rhythm.

With a view to the possibility that this arrhythmia might be ascribed to a lesion in a specific area of the heart, electrocardiograms were grouped into types associated with infarction of the anterior (Q_1T_1) or posterior (Q_3T_3) surface of the left ventricle. It was found that with auricular fibrillation, the infarction was as frequent on the anterior as on the posterior surface of the heart. In five of these cases examined at necropsy the right and left coronary arteries were equally occluded.

Digitalis was administered to two patients after the onset of the auricular fibrillation because of severe heart failure. One of these died suddenly on the eighteenth day (figure 3) and the other developed permanent fibrillation although the heart failure was controlled. Two other patients received digitalis before the onset of the fibrillation but it is not possible to state whether the appearance of the arrhythmia was related to the drug.

AURICULAR FLUTTER

There were three patients with auricular flutter, two of whom died (figures 3 and 4). Heart failure and enlarged hearts were found in each instance and all had had one or more previous attacks of coronary throm-

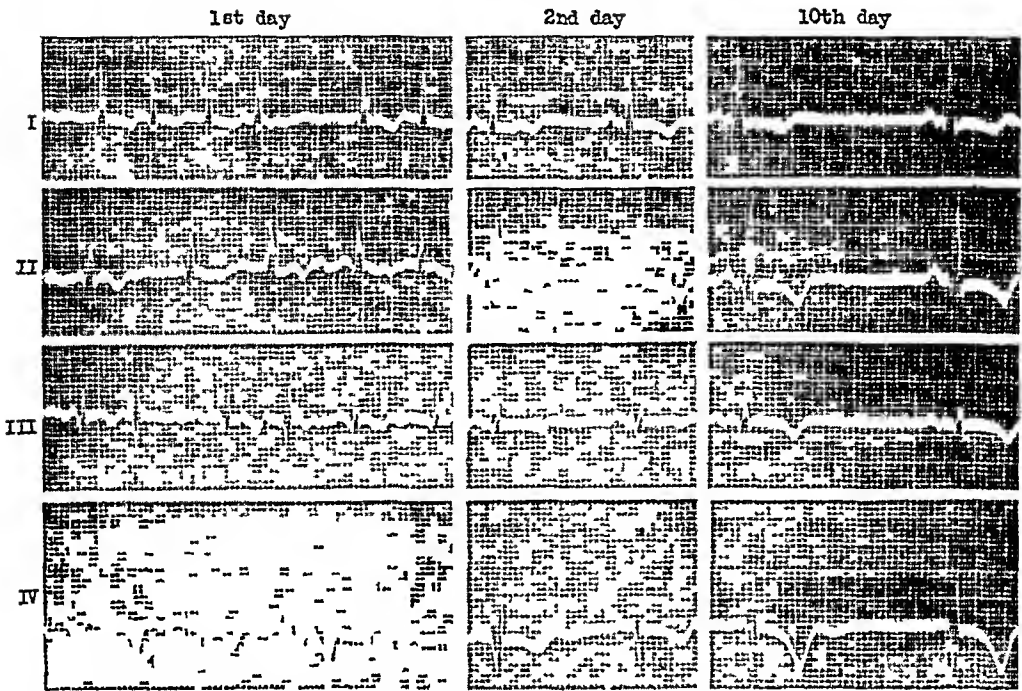

FIG 1 D S, male, aged 61 Acute and old coronary artery thrombosis Recovery

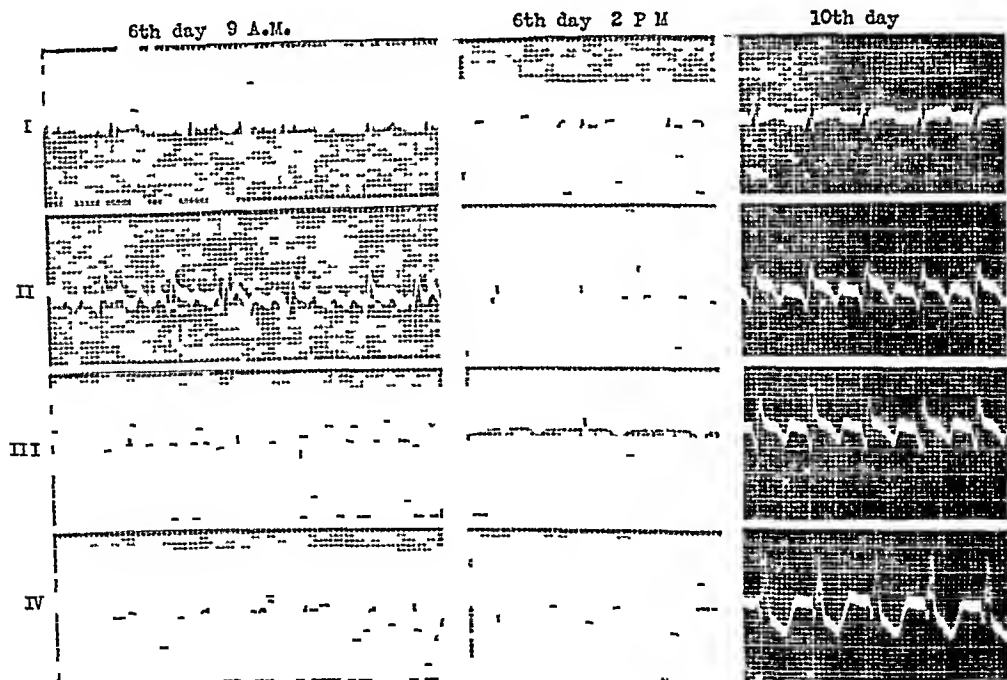

FIG 4 S C, male, aged 58 Old and acute coronary artery thrombosis Paroxysmal auricular flutter Sudden death on thirteenth day

bosis In one of the fatal cases the auricular flutter was a transient episode during auricular fibrillation (figure 3) The two fatal cases had both received digitalis, one during the arrhythmia and one before it set in

NODAL RHYTHM

There were three cases with nodal rhythm and one with wandering pacemaker (figures 5A and 6) All four patients survived, probably because the ventricular rate was normal, between 60 and 70 beats per minute The arrhythmias disappeared without treatment within a week Not all cases of nodal rhythm and shifting pacemaker are due to right coronary artery occlusion as one might expect, for two patients had electrocardiographic signs of anterior wall infarction Thus the S-A node may be compromised by occlusion of the left coronary artery, either by involvement of its nutrient blood vessel or nerve supply

PAROXYSMAL TACHYCARDIA

Paroxysmal tachycardia occurred in nine patients The average ventricular rate was 150 beats per minute Although all nine patients had heart failure and eight an enlarged heart and hypertension, the duration of the arrhythmia was 24 hours or less in eight of the nine, and only two died Of the nine cases, three were auricular (figures 5B and 7), two nodal (figure 8) and one ventricular (figure 9) Although the focus of origin was undetermined in three because electrocardiograms were not obtained during the arrhythmia, the clinical appearance was that of an auricular tachycardia

A word should be added concerning ventricular tachycardia With constant supervision and frequent electrocardiograms it was observed only once in the 300 cases examined* Its duration was extremely brief, a few hours, and it remitted without treatment This observation emphasizes the rarity of ventricular tachycardia in man

Only two patients with paroxysmal tachycardia received treatment One with auricular tachycardia who recovered received one dose of 6 grs of quinidine sulphate The arrhythmia ended 10 hours later but probably was not influenced by the drug Another patient with nodal tachycardia was given 54 grs of quinidine but died of a cerebral embolus four days after cessation of the tachycardia

HEART BLOCK

Although increased P-R intervals occurred very often, incomplete heart block with dropped beats or complete A-V dissociation was found but eight times in the 300 cases Three patients had complete heart block alone with

* Since these data were collected, two other cases of ventricular tachycardia have been observed In one, a 42 year old woman, the arrhythmia persisted despite quinidine therapy by mouth and intravenously and the patient died after two days Septal infarction without recent thrombosis was found at post mortem In the second case, a male aged 38, the tachycardia lasted about one day and ceased spontaneously The patient recovered

ventricular rates between 20 and 40 beats per minute (figure 10) They all had hypertension, an enlarged heart and heart failure These patients all died within three days after the onset of the arrhythmia In two other patients the arrhythmia varied between incomplete and complete heart block, one of these died of heart failure soon after the rhythm had returned to normal Finally, there were three patients who had incomplete heart block alone The ventricular rate in these cases was higher, 50 to 100 beats per minute, and all three survived In one, the incomplete heart block was still

FIG 10 C B, female, aged 72 Coronary thrombosis Complete heart block and auricular fibrillation Death on fourth day P M Right coronary thrombosis Infarction posterior left ventricle and septum

present one year after the attack In the other two, normal sinus rhythm returned gradually within one week

Four of the five patients with complete heart block came to postmortem examination and in each instance there was occlusion of the right coronary artery with infarction of the posterior wall and septum, with or without occlusion of the other arteries, findings which confirmed those of previous investigators^{22, 38, 44, 67, 68} who had noted the association between complete heart block and this specific pathological lesion

One patient with complete heart block received adrenalin before admission to the hospital but with no effect One patient who showed both com-

plete and incomplete heart block at different times received atropine and ephedrine sulphate, again with no effect. The three patients who had incomplete heart block received no treatment and survived.

The heart rate in this group of cases deserves emphasis. The three patients with complete heart block who died were semi-comatose with rates between 20 and 40 beats per minute when admitted to the hospital. We believe that in these cases the outcome depended on the ventricular rate, when it is below 40, the prognosis is poor.

ASSOCIATION OF ARRHYTHMIAS

In three cases two or more significant arrhythmias (figures 3 and 5) were associated and in 10 cases a significant arrhythmia was associated with multiple premature beats as, for example, a ventricular bigemini interrupted by paroxysms of auricular tachycardia (figures 7 and 9). One patient developed nodal rhythm during the first week of his illness, auricular fibrillation during the second week and auricular tachycardia during the third week (figures 5A and 5B).

NORMAL HEART RATE

In 134 patients (44.6 per cent) the heart rate throughout their illness was between 61 and 100 beats per minute (table 2). Enlarged hearts and heart failure were found in only one-half of these, an incidence less than the average of our series. The majority of patients were in their first attack of thrombosis. The mortality rate was only 6 per cent. Therefore, a patient whose heart rate does not go above 100 beats per minute has a very good outlook.

TABLE II
Heart Rate in 300 Cases of Coronary Thrombosis

| | Normal Heart Rate | Sinus Tachycardia | Sinus Bradycardia |
|--------------------------|-------------------|-------------------|-------------------|
| No. of cases | 134 | 158 | 70 |
| Incidence | 44.6% | 52.6% | 23.3% |
| Average age | 55 | 57 | 54 |
| Ratio—male:female | 4:1 | 3.6:1 | 10.7:1 |
| Previous attack | 44.0% | 50.0% | 38.6% |
| Previous hypertension | 61.9% | 65.8% | 60.0% |
| Enlarged heart | 48.5% | 69.6% | 42.8% |
| Heart failure | 53.9% | 84.2% | 47.1% |
| Mortality | 6.0% | 39.9% | 2.8% |
| Average ventricular rate | 61-99 | 100-150 | 46-60 |

SINUS TACHYCARDIA

We have emphasized in a previous study⁶⁹ the importance of tachycardia both as a prognostic sign in coronary thrombosis and as an index of the

degree of heart failure. When the cardiac rate rose above 100, the incidence of cardiac enlargement and heart failure as well as the mortality rate rose, 40 per cent of these cases ending fatally (table 2). The significance of heart rate is particularly evident in those with a rate of 120 or more, heart failure was almost universal and the mortality rate 54 per cent as against 29 per cent in the group with a rate 100 and 120. As previously stated, in patients with a rate between 60 and 100, the mortality rate was only 6 per cent.

SIMPLE BRADYCARDIA

A study of the clinical course of those patients whose heart rate at any time during the attack of coronary thrombosis fell to 60 or below, excluding cases of heart block, is of interest (table 2). These patients did extraordinarily well, and heart failure and mortality rate were minimal. In fact, none of the eight patients whose rate was between 40 and 50 and only two of the 62 whose rate was between 50 and 60 died. The average age of these patients was slightly lower than the average for the series, the majority had sustained their first attack and the incidence of enlarged hearts and heart failure was low.

SYMPTOMS

The onset of an arrhythmia in patients with coronary thrombosis may be of considerable diagnostic significance. Occasionally, it is the first, perhaps the only, sign of the presence of thrombosis, corroborated by electrocardiogram. Therefore, even in the absence of pain, the sudden appearance of an arrhythmia may warrant a tentative diagnosis of coronary artery thrombosis.^{13, 22, 25} The arrhythmia may occasion no symptoms other than palpitation. However, when the ventricular rate is very rapid, the coronary circulation of a heart already severely damaged may become so embarrassed as to cause precordial pain and shock which simulate another acute coronary artery thrombosis.⁷⁰⁻⁷³ In our series, two patients who were recovering from the effects of an occlusion suddenly suffered a recurrence of severe precordial pain and shock. Electrocardiograms during this episode showed in one case (figure 2) auricular fibrillation with a ventricular rate of 150-200 and in the other (figure 5B), auricular tachycardia with a ventricular rate of 170, in addition there were definite R-T deviations characteristic of acute infarction. However, the diagnosis of another acute thrombosis had to be given up when within 24 hours the condition of the patient and the electrocardiogram spontaneously resumed their former status after regular sinus rhythm and a slow rate had returned.

The effect of a very slow ventricular rate, as in complete heart block, may also manifest itself clinically by syncope, convulsions and coma, that is, the Stokes-Adams syndrome. In our experience and that of most authors, the latter is rare in coronary artery thrombosis. However, Schwartz⁴⁴

recently described 15 such cases, although it is possible that not all had coronary thrombosis as the diagnosis could be confirmed by electrocardiogram or necropsy in only a few cases. One of our patients with heart block entered and died in coma, and two others in semi-coma, in the former, an associated cerebral vascular lesion could not be ruled out. Another point not to be overlooked, as Levine²² has emphasized, is that syncope in coronary thrombosis may result from insufficient cerebral circulation as a result of severe collapse. Such an occurrence was observed in one patient of our series.

Levine²² was the first to point out the rarity of coronary artery thrombosis in patients with auricular fibrillation, he observed only one such case and in this the diagnosis was uncertain. Parkinson and Campbell⁷⁴ in 200 cases of paroxysmal auricular fibrillation found 12 associated with coronary thrombosis but in only two was the arrhythmia present before the acute attack. Brown⁷⁵ studied the incidence of coronary thrombosis in patients with auricular fibrillation and coronary sclerosis and found only two instances in 119 cases. In a similar study of 158 hypertensive patients with fibrillation Flaxman⁷⁶ found only three instances of coronary artery thrombosis. In our own series auricular fibrillation may have been present preceding the attack in two patients. The explanation for this antagonism between auricular fibrillation and coronary thrombosis is not clear to us.

THE MECHANISM OF PRODUCTION OF ARRHYTHMIAS IN CORONARY ARTERY THROMBOSIS

When one considers the multiplicity of effects of coronary artery closure on the heart, it is not surprising that arrhythmias are often a complication. In the present state of our knowledge it is, of course, not possible to explain each arrhythmia with certainty. However, certain factors, such as *anoxemia*, *impaired nutrition* or *altered metabolism* of the heart muscle, *increased irritability*, *nervous reflexes*, *anatomical lesions* and *heart failure* are important in initiating any arrhythmia and all these are present to a striking degree in coronary artery thrombosis.

It is impossible to separate anoxemia and impaired nutrition or metabolism of the heart muscle. The effect of coronary thrombosis is not confined to the local area of infarction but disturbs the function of the heart as a whole. During the acute stage of shock there is a marked diminution of cardiac output and mean blood pressure and not only is there a local block in the coronary circulation at the site of the thrombosis, but the blood flow to the rest of the myocardium is reduced. The nutrition of the heart suffers, its metabolic activities are interfered with, and as Neuhof⁶⁴ early pointed out, such disturbances in the auricular musculature produce differences in refractory periods and delays in conduction which may throw the auricles into fibrillation. Carter and his coworkers⁷⁷ emphasized the relation between anoxemia and cardiac irregularities, particularly in coronary throm-

bosis Anoxemia leads to the local accumulation of lactic acid which interferes with the development of the excitatory process and its normal propagation. Thus there may be a local area in which diminished conductivity or spontaneous excitation gives rise to an ectopic rhythm. In particular, anoxemia may decrease the refractory period in the auricles leading to the circus movement of auricular fibrillation and flutter. Carter refers also to the earlier observations of Greene and Gilbert⁷⁸ who, following rebreathing experiments in men and in animals, noted great slowing of rate, shifting pacemaker, nodal rhythm and progressive delay in A-V conduction. They emphasized the sensitivity of the S-A and A-V nodes to anoxemia but believed that the effect of anoxemia might be an indirect one through the vagus nerves. Resnik,⁷⁹ too, found that the S-A and A-V nodes and auricles were especially sensitive to anoxemia with the consequent slowing of the heart and shortening of the refractory period which predispose to auricular fibrillation.

Another mechanism for production of cardiac irregularity is the *irritability* of the local area of infarction, from which abnormal impulses or reflexes may arise. The area of infarction is a region of diminished blood supply, dying muscle and surrounding inflammatory reaction. As Condorelli⁸⁰ and Froment⁸² have emphasized, it is a question whether the dying muscle or the surrounding inflammatory tissue acts as the irritable focus for the initiation of ectopic beats. Not only may the area of infarction initiate abnormal impulses but it may also interfere with the orderly conduction of the excitation wave through the ventricles. Further, abnormal *reflexes* may arise from this irritable focus either directly or as a result of anoxemia. The importance of the *vagus nerve* in these reflexes was demonstrated by Greene and Gilbert⁷⁸ who were able to abolish the arrhythmias due to anoxemia in dogs by cutting the vagus nerve. Some authors,^{55, 62, 81, 82} finding ventricular tachycardia commonly associated with septal infarction, have suggested that damage to the septum and conduction system as well as local irritability are necessary for the production of ectopic rhythms of this type.

The importance of the various factors discussed above is appreciated when it is realized that, except in complete heart block, there is no correlation between the exact site of thrombosis or infarction and the type of arrhythmia. Since the right coronary artery supplies the A-V node and the bundle of His in 90 per cent of cases and the auricles and S-A node in 60 per cent of cases (Gross⁸³), one would expect that occlusion of this artery would produce bradycardia, nodal rhythm, various degrees of auriculoventricular heart block and auricular fibrillation, flutter or tachycardia, and that the occurrence of these complications would be infrequent with closure of the left coronary artery which supplies the auricles in 20 to 40 per cent of cases and the A-V node rarely. Yet all these arrhythmias, except complete heart block, occurred as often with occlusion of the left as the right artery. When heart block was present, the right coronary artery was almost always

involved, both in our cases and in those reported in the literature^{44, 68} In the occasional cases in which thrombosis of the left anterior descending artery was associated with heart block, it is possible that this vessel and not the right coronary supplied the junctional tissues or that the right coronary artery was already markedly sclerotic and stenosed and that the greater part of the circulation to the junctional tissues had been supplied by anastomotic vessels from the left coronary artery

In recent discussions, the relationship of *heart failure* to arrhythmias, particularly auricular fibrillation, has assumed a prominent place Luten^{81, 85} stated that the tachycardia which occurs in heart failure is a compensatory mechanism and that auricular fibrillation, when it occurs, usually is secondary to and not the cause of heart failure He believes that in the presence of auricular damage, dilatation and stretching of the auricular wall from increased intraauricular pressure in ventricular insufficiency is the predisposing factor in the production of auricular fibrillation The same explanation could be applied to auricular flutter and auricular tachycardia Vaquez⁸⁶ and Nahum and Hoff⁸⁷ also thought that auricular distention was responsible for the frequent association of auricular fibrillation and heart failure

In a number of cases we have been able to study the validity of this mechanism of heart failure and auricular distention in coronary thrombosis (table 3) We have already found⁶⁹ that heart failure occurs in the

TABLE III
The Relation of Auricular Fibrillation to Heart Failure in Coronary Thrombosis

| Case | Day of Attack | Rhythm | Ventricular Rate | Circulation Time—Sec | Venous Pressure—cm | Vital Capacity—c c | Clinical Heart Failure | |

majority of patients with coronary thrombosis Infarction and failure of the ventricles place a strain on the auricles which dilate Auricular dilatation may be seen experimentally and is also suggested by the appearance of large P-waves in the electrocardiogram⁸⁸ While most of our cases of auricular fibrillation and paroxysmal tachycardia were associated with heart failure, fibrillation occasionally occurred when there was no clinical evidence

of failure or when objective tests, such as the circulation time, indicated only a mild degree (Case 1). Sometimes, auricular fibrillation persisted when heart failure had entirely or largely disappeared (Case 2). Yet, in several instances, even with rapid ventricular rate it spontaneously remitted to normal rhythm in the presence of unchanged or increasing failure (Case 3). This was true in eight of the nine cases with paroxysmal tachycardia. One patient who entered the hospital with definite failure following coronary occlusion developed auricular fibrillation with rapid ventricular rate on the fourth day. During the next 24 hours the failure became advanced and the patient died the following day, yet the arrhythmia spontaneously gave way to sinus tachycardia the day before death. In addition, many of our severest cases of heart failure were associated with regular sinus rhythm. Hence we believe that although heart failure with dilatation of the auricles probably exerts an important influence in the initiation of arrhythmias in coronary thrombosis, many other factors come into play.

Since thrombosis always occurs in patients with diseased coronary vessels, chronic pathological changes which may be significant in the onset of an arrhythmia are usually coexistent. Further defective nutrition of this diseased heart muscle consequent on infarction may produce irregularities. Because of the hypertension so commonly found in coronary thrombosis, especially in patients with arrhythmias, myocardial fibrosis is particularly marked. Moreover, hypertension itself may predispose to arrhythmias. Coronary artery disease alone has not been considered a significant etiological factor in the permanent type of auricular fibrillation in non-valvular heart disease, but rather hypertension^{32, 75}. Brown⁷⁵ found that in coronary artery disease auricular fibrillation was rare unless preceding hypertension was present. No specific pathologic lesion has been found in the auricles even in permanent fibrillation and frequently, no lesion at all^{32, 74, 89}. It seems reasonable to assume that such is the case following acute coronary occlusion.

Ventricular tachycardia deserves special comment. Its rarity in coronary thrombosis in man is in marked contrast to its frequency in experimental coronary ligation⁶⁻¹². Experiments in dogs have emphasized unduly the significance of this arrhythmia with the result that single case reports⁴⁶⁻⁵⁹ have been considered worthy of publication, thus centering attention on the association of coronary artery thrombosis with ventricular tachycardia. Actually, it is one of the rarest of the arrhythmias and occurs only once in several hundred cases. It should be remembered that experimental ligation produces a sudden change in an animal with normal arteries while in man the occlusion caused by coronary thrombosis is gradual and accompanied by compensatory anastomoses produced by previously sclerotic vessels. In the majority of instances in which ventricular tachycardia has been observed in coronary thrombosis it has followed administration of digitalis^{42, 49, 82, 90, 91}. This is doubtless more than a coincidence since digitalis increases the irri-

tability of the heart muscle and in coronary thrombosis where irritability is already great, it may act as a predisposing factor. In fact, during the past few years since the danger of digitalis in infarction has been recognized and the drug withheld, ventricular tachycardia has become very uncommon. However, as Gallavardin and Froment^{61, 62} have suggested, when ventricular tachycardia occurs in a middle-aged patient, coronary artery thrombosis is to be considered a likely diagnosis.

We have already stated that the majority of arrhythmias appear within the first three days of the coronary occlusion and spontaneously remit within 24 to 36 hours. This early appearance of the irregularities can probably be attributed to the fact that in the first few days the pathological and physiological changes are most acute and their ephemeral character probably depends on the subsidence of the acute process in the heart muscle and the improvement in the general circulation of the body. Disappearance of edema adjacent to the infarcted area which may be the site of origin of arrhythmia, may lead to rapid resumption of normal rhythm. The enlargement of anastomotic channels already present or the development of new ones is another possible factor in the short duration of the arrhythmias. It has been suggested^{38, 44, 68} that in heart block the diffuse anastomosis around the A-V node between the left and right coronary arteries^{92, 94} may prevent the development of the arrhythmia or prevent it from becoming permanent.

PROGNOSIS

Diversity of opinion exists concerning the prognosis of auricular fibrillation in coronary thrombosis. Christian¹⁷ states "In my experience those patients developing fibrillation have shown a better prognosis than others." Parkinson and Campbell⁷⁴ maintain that auricular fibrillation has no effect on the clinical course and Levine²² found no influence on the mortality rate. Yet Bedford⁹⁵ states that auricular fibrillation adds to the risk of an attack, although it does not preclude recovery, and seven of Howard's²⁷ 10 patients with auricular fibrillation died. Padilla and Cossio⁹⁶ also believe that it is of prognostic significance. Half of our cases with auricular fibrillation ended fatally, a mortality rate more than double that in patients with normal rhythm.

Auricular fibrillation occurred most frequently in severely ill patients with an advanced degree of heart failure. How significant the fibrillation itself was in the outcome of the attack is problematic since the irregularity usually lasted but a short time and in half the fatal cases death occurred some time after the cessation of arrhythmia. Furthermore, as we have already pointed out, the transitory fibrillation also occurred in patients with little or no heart failure whose condition steadily improved. It would seem, then, that the importance of auricular fibrillation as a prognostic factor is determined largely by the degree of shock and heart failure present at the

time. However, if a rapid ventricular rate persists, the arrhythmia itself becomes a factor in the fatal issue by increasing the degree of shock and failure. In previous reports^{69, 97} we expressed the opinion that heart block alone of the arrhythmias altered the prognosis of the attack, further experience with a larger series makes it apparent that auricular fibrillation, too, is of serious import.

The conclusions regarding auricular fibrillation also apply to auricular flutter. Yet, in spite of a rapid ventricular rate comparable to that in auricular fibrillation, auricular and nodal paroxysmal tachycardia did not affect the outcome of an attack adversely. Only two of our eight patients died. Although the number of cases is too small to generalize it is probable that the low mortality is explained by the fact that the arrhythmia in seven of the eight patients was of short duration.

Premature beats even when multiple were not of importance unless both auricular and ventricular beats occurred together. But here again, the number of cases is too small to permit conclusions to be drawn. However, most authors have found premature beats of little importance although a few^{12, 66, 103} speak of the inherent danger of multiple ventricular premature beats developing into ventricular tachycardia or fibrillation. Such an association occurred only once in our series.

Complete heart block has been recognized as a very serious irregularity. Karsner¹⁶ states that it usually ends fatally, a fact borne out by the high mortality rate in most of the reported cases and in our series in which it was 80 per cent. However, in occasional instances, recovery does take place, and indeed Schwartz⁴⁴ states that 11 of his 15 cases with Stokes-Adams syndrome due to complete heart block survived the acute attack of thrombosis. The high mortality in complete heart block is undoubtedly associated with the marked bradycardia. In three of our four fatal cases the rate remained below 40 until death. In contradistinction, in both Levine's²² and our own series, partial heart block had no effect on the prognosis. In our three cases the ventricular rate was 50 or more, no Stokes-Adams symptoms occurred and none died.

Since only one case with very fleeting ventricular tachycardia was encountered in our entire series, we are unable to discuss this arrhythmia from personal experience. It has generally been considered a very serious complication. About three-fourths of the cases of coronary artery thrombosis with ventricular tachycardia reported in the literature⁴⁶⁻⁵⁹ ended fatally. The gravity of this arrhythmia may lie in the fact that it usually occurs in patients with severely damaged hearts and large infarcts and that it tends to remain more persistent than other forms of paroxysmal tachycardia.

TREATMENT

Since arrhythmias in coronary artery thrombosis are usually transitory and remit spontaneously, specific therapy, such as *digitalis administration*

advocated by some authors^{13, 21} is not routinely necessary. The general measures employed in coronary thrombosis will usually suffice. These measures which we have fully described in previous articles⁹⁷⁻¹⁰⁰ include meticulous care of the diet, absolute quiet and sedation, particularly with morphine. During the first few days the diet consists of small portions of soft food totalling several hundred calories during the day. Such a regime reduces the work of the heart and avoids gastro-cardiac reflexes. If the condition of the patient improves, the caloric intake is rapidly raised to 800 calories and is maintained at this amount for two or three weeks or more. Fluids are restricted to 1200 c.c. during this period. The first week or two visitors are not allowed and the patient is fed by the attendant. Under this treatment pain usually disappears after the first or second day and the patient is comfortable. When heart failure, frequently present soon after the attack, increases, diuretics such as mercururin are employed and oxygen if there is cyanosis or dyspnea. We believe, as do most authors,^{22, 42, 101, 102} that digitalis is contraindicated in the first weeks following coronary artery thrombosis. It not only increases the work of the heart but there is a great deal of evidence^{42, 90, 102} that it initiates or prolongs arrhythmias, particularly ventricular tachycardia and auricular fibrillation, when infarction exists. It is possible that the rarity of ventricular tachycardia in our series was associated with the avoidance of this drug. However, in the occasional cases in which auricular fibrillation with rapid ventricular rate persists and increasing heart failure or shock is present, the administration of digitalis may be necessary. Usually one may wait 24 to 36 hours before giving the drug but this will depend on the individual case.

Although we avoided the use of digitalis as a rule, six patients with auricular fibrillation or flutter did receive the drug through error. In three, it was given after the onset of the arrhythmia, two of these died suddenly before the arrhythmia ceased and in the other, fibrillation became permanent. The remaining three cases received digitalis before the onset of the irregularity and one died. In these cases, therefore, digitalis did not prevent or abolish the arrhythmia.

Since Levine^{22, 48, 60, 63} advocated *quinidine* for ventricular tachycardia in coronary thrombosis its use has become very common^{42, 62, 91}, in fact, the prophylactic administration of this drug soon after the onset of the attack to prevent ventricular tachycardia and fibrillation has been advised^{60, 66, 103} particularly if premature beats are present. However, the rarity of ventricular tachycardia in coronary artery thrombosis makes it seem inadvisable to give routinely a drug which may be dangerous. Even if ventricular tachycardia should set in, it may be transitory, as in our single case, or may respond to morphine. If, on the other hand, it persists and heart failure increases, quinidine should be given in sufficient dosage⁶⁰. The intravenous administration should be employed only if the condition is urgent, when it should be given cautiously, that is, slowly and well diluted.⁶³

Auricular and nodal tachycardia almost always remit spontaneously or after the use of morphine. However, if the rapid ventricular rate is associated with increasing failure, in spite of the morphine, quinidine or digitalis should be given. In one of our cases nodal tachycardia ceased after 54 grains of quinidine, however, the patient died of a cerebral embolus four days later.

Levine²² and Schwartz⁴⁴ have advised the use of *adrenalin* when the Stokes-Adams syndrome complicates complete heart block. In spite of the danger of adrenalin in coronary artery thrombosis, this drug should be tried cautiously, because this condition is so serious and without treatment frequently ends fatally. Schwartz reported good results in his cases.

SUMMARY

In this paper we have presented the conclusions drawn from our study of the arrhythmias occurring in 300 cases of coronary artery thrombosis and reviewed the literature pertaining to the subject. Women were almost twice as prone as men to cardiac irregularities.

All types of irregularities were present. Premature beats found in one-fourth of the patients were the most common, but were of little prognostic significance. Other arrhythmias occurred 46 times in 42 patients (14 per cent). Of these, auricular fibrillation comprised one-half. Ventricular tachycardia was rare, occurring only once. There were eight cases of auricular or nodal tachycardia, five of complete and three of partial heart block. In some instances several arrhythmias developed in the same patient.

The arrhythmias may occur at any time but they usually appeared during the first three days following an occlusion. With the exception of nodal rhythm and heart block which may last one to two weeks, they were transitory, more than half remitting spontaneously within 24 hours.

The mortality rate of the patients with a significant arrhythmia, that is, any arrhythmia other than premature beats, was 39 per cent, while for those with regular sinus rhythm it was 22 per cent. This high mortality rate was attributed to the underlying cardiac enlargement, heart failure and hypertension. Half the deaths occurred after the cessation of the arrhythmia. Only very rarely was the arrhythmia itself the cause of death. Half the patients with auricular fibrillation and flutter, and four-fifths of those with complete heart block died, whereas the patients with paroxysmal tachycardia, nodal rhythm and partial heart block usually survived.

The cardiac rate, whether or not the rhythm was regular, was a very significant factor in the outcome of an attack. If the ventricular rate was above 120 or below 40 beats per minute the outlook was poor, when a rate between 60 and 100 was maintained, the patient almost always recovered.

An arrhythmia may be the first and only sign of coronary artery thrombosis, pain being absent or minimal, in fact, the sudden onset of an arrhythmia should suggest the diagnosis of coronary occlusion. On the other hand,

an arrhythmia with rapid ventricular rate may lead to shock and heart failure which may simulate another coronary occlusion

A number of factors probably play a rôle in the initiation of the arrhythmias heart failure with its associated dilatation of the auricles, anoxemia of the myocardium, nutritional or metabolic disturbances and impulses or reflexes originating in and around the infarcted area. Indeed, it is surprising that arrhythmias are not more frequent. Their relative rarity is probably the result of the copious anastomoses throughout the heart, particularly around the A-V node and septum.

Coronary thrombosis is rare when auricular fibrillation is present.

Heart block alone was associated with a specific anatomical lesion in the heart, that is, posterior wall infarction due to right coronary artery occlusion. In the other arrhythmias both the left and right coronary arteries and both the anterior and posterior surfaces of the left ventricle, were involved with equal frequency. The site of acute infarction or chronic fibrosis does not determine the type of cardiac irregularity.

Because the arrhythmias usually remitted spontaneously after a short period we considered specific treatment unnecessary, either prophylactically or after the onset. In fact, digitalis and quinidine are considered dangerous in the treatment of coronary artery thrombosis since they may actually initiate arrhythmias. The rarity of ventricular tachycardia in our series may be due to the fact that digitalis was not used routinely. Only when a persistent arrhythmia produces severe shock or increasing heart failure should they be given. At the onset of an arrhythmia morphine may be administered liberally. Adrenalin should be used in heart block but only when a severe Stokes-Adams syndrome occurs.

THE SURGICAL TREATMENT OF PEPTIC ULCER *

By IRVIN ABELL, *Louisville, Kentucky*

SINCE Billroth, following his successful removal of a carcinoma by pylorotomy in 1881, directed his efforts to the cure of peptic ulcer by surgical measures, a voluminous literature, both medical and surgical, has been accumulated. It is now the consensus of opinion that the problem of the treatment of peptic ulcer is primarily a medical one, assuming surgical significance only with its complications, sequelae and intractable chronicity. The aim of treatment has been to secure a healing of the ulcer or its eradication with a correction of the pathological defects caused by it, together with the institution of such measures as in the light of knowledge and experience are believed to be of value in the prevention of recurrence. In the many types of operations that have been employed, the underlying considerations have been to bring about, as far as possible, a restoration of physiological function, free drainage of the stomach and a partial neutralization of stomach acids by intestinal alkalies.

The occurrence of perforations, bleeding, and malignant degeneration in ulcers left behind, has led to the conviction of the desirability of destroying or removing the ulcer or ulcers in addition to meeting these indications. The wide variation in the degree and character of the lesions encountered in peptic ulcer is such that no single operation suffices to meet the indications in all cases. The attainment of success in its surgical treatment is largely dependent upon three factors: choice of operation, selection of cases for operation, and efficient pre- and post-operative medical management.

For the purpose of discussion, the operative procedures with which we have had personal experience may be classified as conservative and radical. The conservative operations comprised, (a) local excision with cautery or knife followed by suture, (b) local excision plus gastro-enterostomy or pyloroplasty, (c) gastro-enterostomy or pyloroplasty alone. The radical operations consisted in the removal of the ulcer-bearing area by the Billroth I, Billroth II, Polya modification, or sleeve resection methods.

In making a choice of the type of operation to be employed in a given case primary mortality and end results must be the chief considerations. It is obvious that where resistance and vitality have been lowered by long continued disease, marked pyloric obstruction with dehydration and toxemia, inadequate nourishment or continued blood loss, the pre-operative administration of fluids, glucose and blood transfusions are essential in the preparation of the patient for operation, and it is equally obvious that the safety of the patient will be enhanced by the selection of the simplest operation compatible with the correction or alleviation of the pathologic condition.

* Presented at the St. Louis meeting of the American College of Physicians, April 20, 1937.

presented While the roentgen-ray is an invaluable aid in diagnosis, the extent of the local lesion will be revealed by ocular inspection only Quiescent ulcers will permit safer attack than those showing evidence of activity

Perforation into the free cavity or into adjacent viscera, fixation of the duodenum, pylorus and stomach, the presence of inflammatory exudate, recent or calloused, obstruction due to cicatricial contraction, exudative or massive adhesions, location and number of ulcers in varying combinations present problems that are most satisfactorily solved by the selection of that operation best suited to the given case The clinical observation that 90 per cent of gastric ulcers occur at or near the pylorus and along the lesser curvature led Rodman to advocate the resection of the ulcer-bearing area when dealing with ulcers in this location Time and experience have demonstrated the wisdom of this procedure particularly when the ulcers are of the calloused variety Finally a consideration influencing the choice of operation is the efficacy of large resections in the reduction of gastric acidity The observation that following resection of the ulcer-bearing area of the stomach there is a lowering of gastric acidity, and further, that freedom from recurrence is the rule (to which, however there are exceptions), has led to the assumption in some quarters that where there is no acid there will be no ulcer On this hypothesis Finsterer and his followers have practiced the ablation of the acid-bearing portion of the stomach regardless of whether the ulcer be duodenal or gastric, with the avowed intention of producing anacidity We have had no experience with such massive resections other than when necessitated by the location and character of the ulcer, believing the magnitude and extent of the operation to be prohibitive when compared with the favorable results obtained by simpler and less dangerous procedures Furthermore, the presence of hydrochloric acid is essential to the proper physiological action of the stomach and its continued absence, howsoever produced, may be the forerunner of serious secondary disease

The selection of the type of operation to be employed is, and should be, the concern of the surgeon the selection of the case for operation should be the joint concern of the internist and the surgeon While unanimity of opinion is not yet to be obtained, accumulated experience and knowledge permit fairly definite indications for operative treatment The three indications upon which all agree are perforation, hemorrhage, and obstruction

Immediate closure of an acute perforation is the essential indication Approximately 80 per cent of the acute perforations of duodenal ulcers occur on the anterior wall, and 90 per cent of the acute perforations of stomach ulcers occur on the lesser curvature of the prepyloric portion perforation on the posterior wall is frequently sealed by adhesion of adjacent structures Closure of the opening with superimposed layers of Lembert sutures and an omental fat graft suffices not only to control leakage but in a goodly percentage to secure healing of the ulcer as well The employment of additional measures, such as excision or cauterization of the ulcer, py-

loroplasty, gastro-enterostomy or resection of stomach will depend upon the extent, character, and location of the local lesion and the general condition of the patient. The prime consideration in such catastrophes is the saving of life; this is accomplished by the stoppage of the leak. It may be stated as a general rule that the greatest safety to the greatest number prohibits doing more, yet, in the presence of marked pyloric or duodenal obstruction, granting that the condition of the patient permits, a pyloroplasty or gastro-enterostomy may be done with reasonable safety, thus giving assurance of permanent relief and obviating a second operation. If the perforation occurs in a calloused ulcer on the lesser curvature, the infiltration surrounding the ulcer may not only prevent suture but may arouse the suspicion of malignancy as well, in which event excision or gastric resection will be indicated, as the condition of the patient and the judgment of the operator dictate. Perforations in which more or less successful efforts at closure have been made by nature are observed in three clinical groups: one, rather extensive epigastric peritonitis with subhepatic or subphrenic abscess, two, localized peritonitis with recent inflammatory exudate matting together structures adjacent to the perforation, and, three, chronic perforations in which the acute inflammatory phenomena have disappeared and the perforations remain sealed by close adherence of adjacent tissues. In the first two groups, the perforation itself, surrounded and sealed by acutely inflamed tissues, will neither demand attention nor permit surgical attack, the operative treatment consisting in the first group of drainage of the purulent deposits and in the second of gastro-enterostomy. In the third group the location of ulcer and the nature of the structures to which it has adhered will determine the nature and extent of the operation.

Hemorrhage in both gastric and duodenal ulcers occurs in approximately 25 per cent of all cases, appearing usually in one of three forms: (1) More or less constant seepage sufficient to produce anemia, (2) single or recurring hemorrhages of appreciable amount as hematemesis or melena and (3) massive bleeding, which immediately threatens the life of the patient. Ulcers that show constant seepage and recurring hemorrhage of appreciable amount which continues in spite of appropriate medical treatment should be subjected to operation. The type of operation employed should include the destruction of the ulcer, since such ulcers, when treated by conservative operations which do not include their eradication, show in many instances a definite tendency to further bleeding. The treatment which we have employed for massive hemorrhage consists of rest in bed, physiologic rest of the stomach, fluids and nutrition in the form of glucose administered by rectum, subcutaneously, and intravenously, the exhibition of coagulants, chiefly fibrogen by mouth and subcutaneously, and whole blood transfusions. Under this regime the bleeding as a rule will cease, permitting of further study of the patient and a decision for or against operation based upon the associated symptoms, history and laboratory findings. Occasionally a case

will be met in which such measures fail, in which the necessity of controlling the bleeding becomes an indication for immediate operation

The patients with duodenal ulcers that we have selected for operation have presented one or more of four conditions (1) Perforation, both acute and chronic, (2) repeated or long continued hemorrhage, (3) pyloric obstruction, (4) and marked chronicity. A single massive hemorrhage is not regarded as an indication for operation, and in such cases in the absence of the remaining conditions the chance for healing under medical treatment should be afforded until further bleeding or chronicity demonstrates its futility. Chronicity in spite of appropriate medical treatment is accepted as a failure of the latter and an indication for operation. For some unexplained reason duodenal ulcers do not show a tendency to malignant degeneration, hence it has been argued that chronicity alone does not justify resort to operation. The danger of perforation, the menace of hemorrhage, the possibility of obstruction and the continued discomfort produced by the chronic ulcer which proves resistant to an intelligently planned medical treatment afford sufficient grounds to negate this assumption.

The types of operation which we have employed in the treatment of duodenal ulcer are: Excision alone, gastro-enterostomy alone, excision or cautery destruction of the ulcer combined with gastro-enterostomy or pyloroplasty, and resection of the pylorus and duodenum. Resection of the ulcer alone was tried in a small series of cases and abandoned since three patients so treated showed recurrence within a year. Excision of the ulcer with a pyloroplasty, Finney or modified Mikulicz, has been employed for ulcers situated on the anterior wall near the pylorus, showing a minimal amount of duodenal distortion. For the satisfactory performance of this operation it is essential that the pylorus and duodenum be readily mobilized so as to afford opportunity for the necessary manipulation. In the cases conforming to these limitations it has proved a satisfactory procedure.

With increasing experience gastro-enterostomy is less frequently employed alone as the treatment of choice in duodenal ulcer. The destruction of duodenal ulcers is not an imperative indication, but when local conditions make this a feasible and reasonably safe procedure it is advisable in that it at once gets rid of the ulcer, avoiding dependence on a slow healing process, and obviates the possibility of subsequent bleeding and perforation. The eradication of the ulcer is preferably accomplished with the cautery after the method of Balfour. With this technic the bleeding and operative trauma are decidedly less and the destruction of the ulcer just as certain. The cautery wound is closed with Lembert sutures and covered with an omental fat graft, after which a posterior gastro-enterostomy is done. This conservative procedure will meet the indications in the majority of simple duodenal ulcers and the excellent results obtained place the burden of proof upon advocates of other methods to show just cause for such advocacy.

In the presence of obstruction due to cicatrization in the duodenum and pylorus dependent upon ulcer of the duodenum, gastro-enterostomy alone

affords beneficent results, the greater the obstruction the more certain and more complete the relief. Gastro-enterostomy alone is also to be considered where marked periduodenal inflammation has anchored the gut to the liver, and in those cases where age, lowered vitality or obesity contraindicate any direct procedure. When the ulcers are multiple, and they are in from 5 to 6 per cent of cases, when situated on the posterior wall, difficult of access and so calloused as to render healing difficult, and when, so situated, the ulcer has perforated into the head of the pancreas with fixation of duodenum and pylorus to the latter organ, we have come to the practice of resection of the duodenum and pylorus. Ulcers presenting such complicating lesions do not lend themselves to cautery destruction or to excision with pyloroplasty. Our experience with gastro-enterostomy alone in such cases has been disappointing in that persistent gastric discomfort, recurrent bleeding, pancreatitis and pancreatic malignancy have been noted. It is true that the radical operation carries a graver operative risk, but this is justified by the greater assurance of relief.

The indications for the institution of surgical measures in the treatment of gastric ulcers comprise those which apply to duodenal ulcers, namely, perforation, hemorrhage, obstruction and chronicity, to which must be added the danger of malignant degeneration. While malignancy does not become engrafted on chronic ulcer with the frequency which some authors have stated, personal observation has afforded conviction of its occurrence. Patients with frank cancer at the time of examination have given ulcer histories of long duration. Patients upon whom in our earlier experience we had done gastro-enterostomy alone for chronic gastric ulcer have returned years later with gastric carcinoma. This common observation of the tendency of chronic gastric ulcer to undergo malignant transformation would seem to render imperative the destruction or removal of the ulcers in the course of operations undertaken for their relief. The operations with which we have had experience are gastro-enterostomy alone, excision of ulcer alone, cauterization or excision combined with gastro-enterostomy, sleeve resection of the pars media, and resection of the pylorus, antrum, and such part of the pars media as may be necessary to include the ulcer-bearing area. The above mentioned observation of the occurrence of carcinoma in chronic ulcer treated by gastro-enterostomy alone has led us to abandon such conservatism and in the cases selected for this procedure to supplement it with cauterization or excision of the ulcer. In four patients presenting chronic saddle ulcer of the lesser curvature, pars media, a sleeve resection was done. In two of these recurrence was noted and relief obtained by a subsequent gastro-enterostomy. The cases to which the combined procedure of excision or cauterization combined with gastro-enterostomy is applicable are those in which small, resectable ulcers are situated on the lesser curvature, or in the pars media, and also all ulcers situated high on the lesser curvature or posterior wall. Ulcers of the lesser curvature

showing marked inflammatory deposit are best treated by sleeve resection with a gastro-enterostomy, or by pyloric resection, since the defect left by excision or cauterization is such as to render accurate suturing difficult and to produce marked distortion and deformity. Ulcers with a crater of one centimeter or less in diameter are rarely malignant, and are susceptible of conservative treatment, when the craters present larger diameters, the presence of malignancy is to be considered as possible, and unless one feels confident of his ability to distinguish by ocular inspection between simple chronic ulcer and ulcerated carcinoma, or ulcer with beginning carcinoma, the patient should be given the benefit of the doubt and radical treatment employed. Ninety per cent of gastric ulcers occur on the lesser curvature and posterior wall at the pyloric end of the stomach the ulcer-bearing area of Rodman. The presence of inflammatory deposit in the stomach wall around the margin of the ulcer, the presence of perigastric adhesions or of sealed perforation into the liver, pancreas or gastro-hepatic omentum, and the size of the stomach at this point make difficult if not impossible, the employment of conservative excision or cauterization. The probability of failure of healing with a continuation of symptoms and the possibility of perforation, bleeding and malignant transformation, if gastro-enterostomy alone is done, have led to the rather universal acceptance of pyloric resection as the operation of choice in such cases. The Billroth I gives a nearer approach to physiological restoration, when local conditions are such that it can be carried out. In the wider resections the Polya modification of the Billroth II has satisfactorily met the indication.

A proper selection of patients for operation and the use of good judgment in the choice of operation for the given patient combined with dietary and medical supervision for at least one year following operation, offer the sufferer from intractable peptic ulcer, its complications and sequelae an excellent chance for relief. Peptic ulcer may recur after any type of operation, being located at the former suture line or in new locations in the stomach and duodenum, or in the jejunum at or below the site of anastomosis with the stomach. Fortunately, recurrent ulcer is observed in but a small percentage of cases. The cause for recurrence of ulcer is as elusive as that for its primary appearance. Other sources of failure are to be found in faulty operative technic, in leaving behind an infected gall-bladder or diseased appendix, in activation of an unremoved ulcer, in overlooking distant foci of infection, in the resumption of a faulty diet.

Finally, it should be borne in mind that in the vast majority of patients presenting gastric symptoms, the latter are due to causes extrinsic to the gastric tract. Granting the coincidental occurrence of peptic ulcer in such a patient, its treatment is doomed to complete or partial failure in so far as securing freedom from symptoms is concerned, unless the extra-gastric causes of dyspepsia can be eliminated.

REACTION AND SPECIFIC GRAVITY OF THE URINE IN RELATION TO NEPHRITIS (A STUDY OF TEN THOUSAND URINALYSES) *

By EDWIN E. ZIEGLER, M.D., and ARTHUR T. BRICE, A.B.,
San Francisco, California

INTRODUCTION

A STATISTICAL analysis of over 10,000 urine specimens is presented. Special attention was given to the specific gravity of urines in relation to their reaction and to pathological findings.

Some significant correlations have been discovered which may have important clinical applications, especially with reference to the management of nephritis and allied diseases.

The data involved in this report represent consecutive urinalyses performed in approximately a year's time in an active general hospital. The bulk of the urinalyses were single morning specimens from hospital patients. A small fraction were 24 hour specimens. Less than half were single specimens from out-patients.

The specimens from the hospital wards came from approximately 2,270 patients, about two-thirds of whom were surgical cases. The series therefore represents an average of between two and three urinalyses per patient. The great majority of specimens were from males, an almost negligible number being from a small female ward of the hospital.

A fraction of the urine specimens was obtained from persons in normal health. The majority of the specimens were from patients having a large variety of general medical and surgical disabilities requiring hospital treatment.

In view of the fact that acid urines may become alkaline on standing due to bacterial action, all twenty-four hour specimens were preserved with a crystal of thymol. Single morning specimens and out-patient specimens were examined promptly after their arrival in the laboratory. The number of cases which may have had alkaline urine due to bladder retention was insignificant when compared to the large number of specimens involved in this study.

DATA AND EXPERIMENTAL WORK

It is generally held that the normal human urine is acid in reaction. This is stated by all authorities on physiological chemistry, and is undoubtedly true. Of the urine specimens involved in this study 87.4 per cent were found to be acid.

* Received for publication March 17, 1937.

From the Laboratory Center, United States Veterans Facility, Fort Miley, San Francisco, California.

The urine specimens, from which the data presented herewith were obtained, were carefully tested for reaction with good quality red and blue litmus paper and recorded as alkaline, neutral or acid. The specific gravities were carefully determined and recorded.

Of 10,155 urinalyses it was found that 319 specimens were neutral, 961 alkaline and 8,875 acid (table 1).

TABLE I

| | Acid | Neutral | Alkaline |
|-----------------------------|---------------|---------------|---------------|
| Number of specimens | 8,875 | 319 | 961 |
| Per cent of total specimens | 87.4 | 3.1 | 9.5 |
| Mean specific gravity | 1.020 | 1.014 | 1.013 |
| Probable error of mean | ± 0.00005 | ± 0.00025 | ± 0.00015 |
| Standard deviation | ± 0.0047 | ± 0.0046 | ± 0.0048 |
| Range of specific gravity | 1.015-1.024 | 1.010-1.019 | 1.008-1.018 |
| Pathological specimens | 448 | 29 | 106 |
| Per cent pathological | 5% | 9% | 11% |
| Output of solids per liter | 52 gm | 36.4 gm | 33.8 gm |

The average specific gravity of the neutral specimens was 1.0141, of the alkaline group 1.0127, and of the acid group 1.0196. The distribution curve of the specific gravity in each of these groups is shown in chart 1.

CHART I Distribution of 10,000 urinalyses

There was a difference between the neutral and alkaline averages of 0.0014. The standard error of the difference was ± 0.00029 , making the difference 4.8 times the standard error of the difference.

The difference between the means of neutral and acid groups was 0.0055.

The standard error of the difference was ± 0.00255 . This gave a difference 21.5 times the standard error of the difference.

Between the acid and the alkaline groups there was a difference of 0.0069 with a standard error of ± 0.00158 . Thus the difference is 43.6 times the standard error of the difference.

The above figures are highly significant. They show definitely that there is a correlation between the specific gravity and the reaction of the urine. Statistically speaking, when the difference between the means of two series is over two times the standard error of the difference it is regarded as definite evidence of significant difference, and not due to chance.

It has been found that the specific gravity of acid urines is higher than that of neutral urines, and that of neutral urines higher than the specific gravity of alkaline urines. It has been shown definitely that these differences are not accidental, but that they are due to definite factors causing a correlation between reaction and specific gravity of the urine.

Long's coefficient or Haser's method¹ may be used to determine the output of urinary waste products from the specific gravity of the urine. This is done as follows: Multiply the last two figures of the specific gravity by the coefficient of 2.6. This gives the total solids in one liter of urine. To determine the total solids in the 24-hour specimen multiply the above product by the volume of the specimen in cubic centimeters and divide by 1,000. For example let the specific gravity of the 24-hour specimen be 1.012, the amount 1,200 c.c., then

$$\frac{12 \times 2.6 \times 1200}{1000} = 37.4 \text{ gm}$$

If we assume that the average output of urine is 1,000 c.c. for each of the groups (acid, alkaline and neutral), and apply Long's formula, we find that there will be an average of 52 grams of solid waste matter excreted in the acid group, 36.4 grams in the neutral group and 33.8 grams in the alkaline group.

It may be true in some cases when the urine is alkaline and has a low specific gravity there will be a compensatory increase in the urinary volume. The average 24-hour volume for a series of alkaline urines was 2,066 c.c. For a series of acid urines it was 1,611 c.c. Applying Long's coefficient to these average values we find that the excretion of solids would be

| | AVERAGE VALUES | | |
|------------|----------------|------------------|--------------|
| | Volume | Specific Gravity | Total Solids |
| Acid | 1,611 c.c. | 1.020 | 83.8 gm |
| Alkaline | 2,066 | 1.013 | 69.8 |
| Difference | — | — | 14.0 gm |

Thus it is shown in this series that the average amount of excretory solids of the urine is greater in the acid series than in the alkaline. It must be

remembered that here we are dealing with averages. The values in individual specimens may vary greatly.

This indicates that the ability of the kidney to excrete solids and to concentrate the urine is greater when the urine is acid.

It has been common practice for the physician to prescribe alkalis in the treatment of nephritis. Empirical improvement in such cases has unquestionably occurred following alkaline medication. In view of this fact it was determined to study the effect of an alkaline medium on the formed elements of pathological urines. In order to do this the following experiment was performed *in vitro*.

Acid urines containing casts and usually other abnormal findings as albumin, red and white blood cells, were alkalinized with sodium hydroxide. Sodium hydroxide (10 per cent solution) was added drop by drop to the individual specimens until the specimens gave a permanent pink color to phenolphthalein. This gave a pH about 8.4. The alkalinized urine specimens, containing casts, were then incubated at 37.5° C in a water bath for various periods of time. The findings were as follows:

After three hour incubation the casts were partially dissolved. All casts dissolved in the incubated alkaline urines in four hours or more. When potassium hydroxide was used to alkalinize the acid urines in place of sodium hydroxide, the casts were just as effectively dissolved. Other formed elements, especially red blood cells, tended to disappear also but not to the same extent as casts.

Crystals were not especially studied but seemed to be increased in amount on alkalinizing the acid urines.

CHART II Incidence of pathologic specimens in 10,000 urinalyses

Further evidence that there is a correlation between kidney disease and urinary reaction has been found. As shown in table 1, 11 per cent of alkaline urines, 9 per cent of neutral urines and only 5 per cent of acid urines were pathological (chart 2). In this study, urines were listed as pathological which contained one or more of the following constituents: sugar, albumin, casts, red blood cells and pus.

TABLE II

| Specimen | Specific Gravity | Sugar | Reaction | Acetone |
|----------|------------------|-------|----------|---------|
| WES 1 | 1 030 | 4% | Alkaline | Trace |
| ROS 2 | 1 025 | — | Alkaline | Trace |
| CM 3 | 1 029 | — | Alkaline | Trace |
| RJM 4 | 1 028 | — | Alkaline | Trace |
| GFL 5 | 1 035 | — | Acid | — |
| GFL 5a | 1 026 | Trace | Alkaline | Trace |
| HK 6 | 1 029 | — | Alkaline | Trace |

As shown in table 2 there were six urine specimens in the series which were alkaline in reaction and yet showed traces of acetone. This seemed to be a rather unusual finding and it is not explained nor understood. This phenomenon has been reported before by Schrader². It seems to indicate that ketosis can exist even when there is an excess of alkaline salts in the body and urine.

DISCUSSION

The above findings do not support the practice of prolonged alkalinization for nephritis, especially in those cases where there is retention of uremia, since it appears that the ability of the kidney to excrete solids is greater when the urine is acid. However it has been common practice for the physician to prescribe alkalis in the treatment of nephritis and other urinary infections. More recently the advisability of this practice has been questioned.

Since this matter has come to our attention, we have observed a few fatal cases of uremia. The majority of the urinalyses performed on these cases were alkaline in reaction. It is natural to wonder if there is not some relationship between the poor results and the alkaline condition in such cases.

Steele³ has recently recognized the kidney damage produced by prolonged alkaline medication. The alkalis were administered for the treatment of a patient with a gastric ulcer. On correcting the alkalosis the secretory ability of the kidneys improved. There were no clinical symptoms of alkalosis except the kidney damage, indicating that the kidneys are affected before the clinical symptoms of severe alkalosis appear.

Morgan⁴ fed acid, neutral and alkaline diets to dogs in a study of calcium and phosphorus metabolism. It was concluded, among other things, that renal damage may result from the long continued use of alkaline diets. This important experimental work was discussed in an editorial in the *Journal of the American Medical Association*⁵.

Berger and Binger⁶ report seven cases of alkalosis resulting from alkaline treatment of peptic ulcer. In all seven cases impaired renal function was demonstrated during alkalosis. After the alkalosis had been corrected, evidence of impaired renal function persisted in five of the seven cases, thus indicating that permanent renal damage may result from alkalosis.

In addition to the alkaline medication in cases of advanced nephritis, patients are often given an alkaline diet, consisting usually of fruit juices which further alkalinize the urine^{7 8 9} Fruits on being ashed yield alkaline salts predominately and are therefore alkaline ash foods

It often happens that patients will continue alkaline self-medication after the physician has advised its discontinuance Many people are known to take alkaline medicines for long or short periods without medical advice It is obvious that such self-medication with alkalis is not without danger The public is being induced to engage in alkaline self-medication by many commercial interests through various popular means of advertising

In view of the evidence that has been accumulating on the harmful effect of prolonged alkaline medication, it is obvious that the above mentioned commercial exploitation of alkaline waters, crystals and drugs is not in the public interest Alkaline medication, like any other medication, should be under the control of the physician The tendency to regard alkaline self-medication as harmless should be combated by the medical profession There is no sound reason why sodium bicarbonate should be a household remedy any more than hydrochloric acid

In view of the above evidence that alkalis diminish the ability of the kidneys to concentrate the urine it would seem necessary to take this into consideration in performing and interpreting tests such as the Mosenthal and other kidney function tests

In spite of the above consideration, the empirical administration of alkalis seems in some cases to have a temporarily favorable effect on nephritis An explanation of this is suggested by some experiments, *in vitro*, reported above In these experiments acid urines which contained casts were alkalinized with sodium hydroxide and after four hours' incubation, the casts were dissolved These findings seem to justify the alkalinization of the urine in cases of nephritis with casts The good effect of the alkalinization is probably due to the solution of casts in the kidney tubules, thus opening blocked tubules Prolonged alkalinization would not appear necessary to accomplish this purpose, inasmuch as casts are dissolved in alkaline urines in about four hours time *in vitro* Prolonged alkalinization is further contraindicated because of the danger of causing alkalosis and kidney damage as shown by various workers

Aside from dissolving casts the administration of alkalis would seem to be contraindicated Many investigators in recent years have shown that acid urines are bacteriostatic and in some cases even bactericidal whereas neutral and alkaline urines are not

THE ACID REGIME IN TREATMENT

The practice of giving acids, acid salts and acid ash foods seems to be indicated in cases of nephritis where there is inadequate excretion of waste products

Acid ash foods (especially meats), have been indicted as etiological factors in the causation of nephritis, but up to the present time, there has been no generally accepted experimental work to show that the acid ash foods and the acid salts which they contain, namely sulphates, chlorides and phosphates, can cause nephritis. On the contrary, evidence has been accumulating to show that acid ash foods and acid salts have a favorable influence on nephritis and on urinary infections.

The acid foods are those which contain an acid ash—meats, game, seafood, fish, eggs, grains, cheese and some nut meats.

Thomas¹⁰ studied the Eskimo during the MacMillan arctic expedition of 1926. He found that the Greenland Eskimo living on an exclusive acid ash diet, consisting entirely of meat, had no increased tendency to vascular or renal disease. On the other hand he found that the Labrador Eskimo who ate cooked meat with many prepared, dried and canned fruits and vegetables was very subject to both vascular and renal diseases.

In 1931 Lashmet¹¹ reported the treatment of nephritic edema by acid. He found that the administration of hydrochloric acid or ammonium chloride decreased the edema while neutral chlorides as sodium chloride, did not. In regard to diet, he found that an alkaline ash intake increased nephritic edema while an acid ash diet decreased the edema.

The above mentioned work of Lashmet, showing that acid medication and acid ash foods reduce nephritic edema is revolutionary to modern medical practice. In the light of evolution, however, it seems physiologically reasonable. Primitive man was nomadic and existed on acid-ash foods almost exclusively, namely, meat, fish and eggs, and later, grains. Thus the human kidney is phylogenetically adapted to excreting acid urine. This tends to class man nearer to the carnivora with acid urinary excretion than to the herbivora which excrete alkaline urine.

Tables of acid ash foods and of alkaline ash foods are available in standard works for those who are interested in this matter. Such lists are given by Sherman¹², Hawk and Bergeim¹³ and by Manville and Winchell¹⁴. The latter give an extensive list which was compiled from several sources.

Those who are interested in the clinical symptoms of alkalosis are referred to a recent article on "Alkali Poisoning" by Cope¹⁵. This author suggests the use of hydrated magnesium silicate in place of soluble alkalis for treating gastric ulcer. An abstract of this work appears in the *Journal of the American Medical Association*¹⁶.

Favorable reports on the treatment of urinary infections with ketogenic diets have appeared. It is suggested that perhaps the good results may have been due to the acid-ash diets used rather than to any ketone bodies that may have been formed.

The inorganic acid salts of acid-ash foods would be more effective in reducing the pH of the urine than the ketone bodies derived from lipoids. Furthermore, it is practically impossible to produce actual ketosis in non-diabetic individuals.

Ketone bodies can be present in alkaline urines. It was found that out of 961 alkaline urines, six showed a trace of acetone (table 2). The specific gravity of these specimens was unusually high for alkaline urines, indicating an unusual excretion of waste products. This phenomenon has been reported previously by Schriader.² No explanation is offered for this comparatively rare phenomenon. However, its occurrence suggests that acidosis and ketosis are separate and not necessarily related conditions. Ketone substances are derived from the incomplete oxidation of fats. Whereas acid substances such as the acid salts (chlorides, sulphates and phosphates) which give the urine its normal acidity, are derived from acid-ash foods of the diet and the catabolism of tissues. The specific rôle of foods in relation to the composition of the urine, has been comprehensively studied by Blatherwick.¹⁷

It is obvious from the foregoing that the inorganic mineral ash of foods does have a definite effect on the body chemistry and has important relationships to disease. Acid ash foods and alkaline ash foods as well as acid and alkaline medicines, deserve extensive further study in this regard.

It appears from this and other investigations that excessive alkaline intake has a deleterious effect upon the kidneys and that this effect can appear before symptoms of clinical alkalosis develop.

SUMMARY AND CONCLUSIONS

- 1 The ability of the kidney to excrete solids and to concentrate the urine is greater when the urine is acid than when it is alkaline or neutral.

- 2 Acid urines show fewer abnormal findings than alkaline and neutral urines.

- 3 Prolonged alkalinization of the urine apparently produces kidney damage.

- 4 Temporary alkalinization of the urine is apparently of service in dissolving casts and thus opening blocked kidney tubules.

- 5 Alkaline self-medication should be discouraged.

- 6 Alkaline medication, as well as acid medication, should be controlled by the physician.

- 7 Acid types of therapy may prove superior to alkalinization in the treatment of nephritis and its complications as well as in other urinary infections.

- 8 A definite correlation has been demonstrated between the reaction of the urine and its specific gravity. Acid urines generally have a higher specific gravity than alkaline or neutral specimens and therefore remove more waste products from the body.

The authors wish to acknowledge the technical assistance of Mr. Dale B. Frost, who performed the urinalyses which furnished the data for this paper.

PROBLEMS CONNECTED WITH THE USE OF PROTAMINE-ZINC-INSULIN *

By HENRY T RICKETTS, M D , *Chicago, Illinois*

THE efficacy of protamine insulin in the treatment of diabetes has been convincingly demonstrated by a number of workers ^{2 3, 6, 9, 11, 12, 13, 14, 15, 18, 19} during the past year. Its superiority over the old insulin as evidenced by better control of the blood sugar, fewer reactions, reduction in the number of daily injections and often an appreciable saving in total requirement cannot be doubted.

All investigators † have recognized, however, that the slow and prolonged action to which protamine insulin owes its conspicuous advantages is also responsible for certain difficulties peculiar to its use. It seems appropriate at this time, therefore, with the new material recently placed on the market, to report an additional series of cases with the specific purpose of redirecting attention to these problems and outlining methods of meeting them.

This study is based on experiences with the administration of protamine insulin to 26 diabetic patients. Of these, five were children. The disease was classified as severe in 12 cases, moderately severe in nine and mild in five. Of 20 patients who were first given protamine insulin in the hospital, 19 were transferred from regular insulin and one patient was treated with the protamine compound alone. In all of the hospitalized cases several determinations of the dextrose content of the blood and urine were made daily, usually before breakfast and from three to four hours after each meal. Of the six patients who were first given protamine insulin in the out-patient department, four had been taking regular insulin and two had received none.

One house physician was forced to return to regular insulin before he had become stabilized because of marked hyperglycemia alternating with severe reactions which interfered with the performance of his duties. Another patient was carried through pregnancy with protamine but was given regular insulin alone at delivery and for four weeks thereafter in the fear that the action of the former might prove too slow and inflexible to meet the rapid fluctuation in tolerance incident to parturition and lactation. With these two exceptions no patient who has started the use of the new insulin has discontinued it, and all but one have returned at frequent intervals for analyses of the blood or urine or both.

* Read in part before the Chicago Society of Internal Medicine, February 22, 1937.

From the Department of Medicine of the University of Chicago.

The author is indebted to Dr. Walford Swanson for the privilege of studying five children in the Bobs Roberts Memorial Hospital, and to Dr. Maurice Glock, Miss Vivian Iob, Miss Mabel Egan and Miss Louise Klein for numerous determinations of the blood sugar.

For the sake of simplicity the term "protamine insulin" will be used in place of protamine-zinc-insulin except where otherwise indicated.

† See especially the communication by Allen ¹

Because of the great advantage in convenience an effort was made, successfully in all but one case,* to control the blood sugar by a single daily injection of protamine insulin given an hour or so before breakfast, either alone or in combination with a small, simultaneous dose of regular insulin. The following remarks apply particularly to this form of administration.

It should be stated in all fairness that the accompanying charts represent juvenile or relatively severe adult diabetics whose management by any method would not be easy, and they have been chosen for presentation here because they illustrate the difficulties with which any physician undertaking treatment with protamine insulin may have to contend. In the milder cases of the present series, as in other reported series, good results were obtained with much less effort.

HYPERGLYCEMIA AFTER MEALS WITH NORMAL OR LOW BLOOD SUGARS DURING THE NIGHT

The difficulty most commonly encountered in the use of protamine insulin is that, particularly in severe cases, what appears to be the proper dose leads to marked post-prandial hyperglycemia though the blood sugar during the night or in the early morning may be normal or even subnormal (figure 1, July 21, 22, figure 2, June 5, 8, figure 3, Jan 18, 21, 24, figures 4 and 5). Simply increasing the dose in an attempt to take care of the carbohydrate of the meals is apt to result in further hypoglycemia the following morning or before (figure 3, Jan 18, 19, 24, 25, 26). In such a dilemma several courses are open.

(a) The time of administration of the protamine insulin may be pushed back to two or more hours before breakfast. This is inconvenient and in our experience has rarely been satisfactory.

(b) The dietary carbohydrate may be redistributed, one-fifth of the day's allowance being given for breakfast, two-fifths for lunch and two-fifths for supper. Indeed, it has been our recent practice to arrange the diet in this manner on the first day of treatment rather than waiting until the necessity for the change becomes apparent. Such a distribution imposes less of a burden on the slowly acting insulin soon after it is injected, reserving the greater demands for a time when its hypoglycemic effect is well under way, and constitutes a logical basis for the further adjustment of food and insulin which is often necessary.

With the diet apportioned as above and with a given dose of protamine insulin, the patient may react in one of several ways.

1 Control of the blood sugar may be good throughout the 24 hours.

2 The fasting blood sugar may be normal but hyperglycemia still occur after some of the meals. In this event the dose of protamine should not be altered, but a further redivision of carbohydrate must be made. We have been surprised at what small changes sometimes accomplish the desired result.

*This patient required two daily injections of protamine-calcium-insulin. It has not been possible to rehospitalize her for trial with the material containing added zinc.

In the case of R B (figure 1, July 22, 23), for example, the subtraction of only 5 grams of carbohydrate from breakfast and its addition to supper spelled the difference between poor and good control. Since the fasting blood sugars on July 21 and 22 were already normal, the slight increase in the dose of protamine on the

Effect of small changes in insulin dosage and carbohydrate distribution

FIG 1 Protamine-zinc-insulin is indicated by figures within circles followed by "Zn". Regular insulin in succeeding charts is shown by figures without circles. The third line shows the distribution of dietary carbohydrate (not total glucose value) between breakfast, lunch, supper and bed time. The shaded area represents the average normal range of blood sugar for the method used. In this case post-prandial hyperglycemia was well controlled by small changes in carbohydrate distribution and dosage of protamine insulin. The dose, however, need not have been increased since the blood sugar during fasting was already normal. Note symptomless hypoglycemia on Jan 28, when the blood sugars were obtained in the out-patient department.

twenty-third and twenty-fourth was probably superfluous and, indeed, led to mild hypoglycemia.

The case of A F (figure 2) is similar. The division of carbohydrate in the proportion of 20-40-40 on June 6 resulted in hypoglycemia before lunch. On June 8 the ratio of 30-40-30 was unsatisfactory. The mean of 25-40-35 reached on June 10, however, gave adequate control throughout the day.

In principle, obviously, carbohydrate should be deducted from the meal following which hyperglycemia occurs, and added to the meal following which the blood sugar is low. Our experience with patients who are sensitive to such small shifts in carbohydrate is at variance with that of other writers^{9, 12, 13, 18}, who imply that with protamine insulin considerable latitude in diet is permissible.

3 The fasting blood sugar may be too low, with or without glycosuria

during the day In this case, either (1) the dose of protamine must be reduced until the morning blood sugar is normal, any resulting daytime hyperglycemia being cared for by dietary adjustment, or (2) the dose of protamine may be kept the same and a bed-time feeding of 10 to 30 grams of carbohydrate given If glycosuria occurs after meals, the bed-time carbo-

FIG 2 Though well controlled when discharged from the hospital (June 10), increased activity at home led to early morning hypoglycemia which necessitated a bed time meal The distribution of carbohydrate (30-35-35-20) which gave an unsatisfactory curve on Jan 25 has now been changed to 25-40-40-15 with good results The letter R in this chart and succeeding ones indicates insulin reaction Note symptomless hypoglycemia on Jan 25

hydrate should be obtained by deducting small amounts from the meals at the times indicated rather than by adding it to the total daily allowance, the latter procedure is apt to result in an increase in the total insulin requirement If, on the other hand, post-prandial hyperglycemia does not occur on the given dose, the carbohydrate taken on retiring may be added to the total daily allotment with only slight, if any, change in the dose of protamine About two-thirds of the patients in this series have required a bed-time meal

The case of H G (figure 3) illustrates some of these points The total diet of carbohydrate 150 grams, protein 75 grams and fat 120 grams was maintained throughout On Jan 19, with the carbohydrate distributed 50-50-50, 35 units of protamine insulin, following the 10 units of regular insulin given the evening before, proved to be too much The dose was accordingly dropped to 25 units, and since the highest blood sugar on the nineteenth had occurred before lunch, the carbohydrate

was divided 30-60-60 It is apparent from the blood sugar curve of January 21 that now the breakfast was too small and the lunch and supper were too large Therefore the diet was rearranged by adding 10 grams of carbohydrate to breakfast and subtracting 20 grams from lunch and 10 grams from supper, the extra 20 grams thus

FIG 3 This patient was transferred to protamine insulin at the time when her tolerance for carbohydrate was improving after recovery from a cold This procedure under such circumstances is often attended by difficulty It was a mistake to attempt to control afternoon and evening hyperglycemia by raising the dose of protamine insulin on Jan 19 and 24 because the dose of the preceding day in each case had already produced hypoglycemia before breakfast Note progressive improvement in blood sugar curves from Jan 24 to 26 despite no change in carbohydrate distribution or dosage For further discussion see text

obtained being given at bed-time The resulting proportion of 40-40-50-20 was found satisfactory except for the persistence of early morning hypoglycemia This was due to the erroneous increase in the dose of protamine from 25 to 30 units between January 21 and 24 in a mistaken effort so to control the day-time hyperglycemia exhibited on the former date When the dose was reduced to 20 units hypoglycemia was eliminated (January 29)

It may be stated here that the distribution of protein and fat between the various meals is unimportant Also, in common with Campbell³ we have found the lower carbohydrate diets more satisfactory than those of higher value

4 The blood sugar throughout the day, including that before breakfast, may be maintained on too high a level In this relatively happy circumstance the dose of protamine insulin must clearly be increased

5 Only rarely have we observed hyperglycemia before breakfast with hypoglycemia later in the day. In the case of A F (figure 2) the curve obtained on January 24 led to a subsequent change in carbohydrate distribution from 30-35-35-20 to 25-40-40-15, the dose of protamine insulin being left the same.

6 In certain cases, with an amount of protamine insulin which gives a normal blood sugar before breakfast, glycosuria during the remainder of the day may be poorly controlled despite every effort properly to readjust the dietary carbohydrate. This situation usually requires a small dose (5 to 15 units) of regular insulin given at the same time as the protamine. In our experience with this group of patients to date, the administration of supplementary unmodified insulin before breakfast, provided carbohydrate was properly distributed, has been sufficient to take care of hyperglycemia in the afternoon as well as that occurring before lunch.

The case of J L, a severe diabetic, is illustrative (figure 4). The blood sugar curve obtained on January 21 in the out-patient department shows that a dose of protamine insulin (50 units) sufficient to give reasonable control through the day,

FIG 4 Effect of a small dose of supplementary regular insulin substituted for an equal amount of protamine insulin

produced marked hypoglycemia in the early morning. Reduction of the dose to 45 units corrected the hypoglycemia but resulted in heavy glycosuria after meals. The curve of February 9, with 45 units of protamine and 5 units of regular insulin, is more, though not completely, satisfactory.

The case of T L, also a severe diabetic (figure 5) is similar. Here 7 units of regular insulin were added to the amount of protamine. This, while producing hypoglycemia before lunch, permitted hyperglycemia in the afternoon. The amounts of

protamine and regular insulin, therefore, were continued unchanged, and adequate control was established by changing the proportion of carbohydrate from 25-55-35-20 to 35-45-35-20

FIG 5 Effect of supplementary regular insulin added to the amount of protamine insulin

(c) Since protamine-zinc-insulin has been available it has not been necessary in any case of this series to use the method originally described by Hagedorn of giving regular insulin in the morning and the slowly acting insulin at night

ASYMPTOMATIC HYPOGLYCEMIA

It has been noted by nearly all workers that, probably due to the slowness with which the blood sugar falls, the hypoglycemia caused by protamine insulin is insidious in onset, symptoms may be slight and the level of blood sugar at which symptoms do occur is lower than when regular insulin is used. These facts find confirmation in the cases here reported (figures 1, 2, 3, 4, 5, 6). They may account in part for the common observation that reactions are fewer with protamine than with regular insulin, though it must be admitted that reactions are less frequent also because the blood sugar is better controlled.

We would especially call attention to that group of patients who, though discharged from the hospital well controlled, were found to have abnormally low blood sugars with no subjective manifestations when they were recalled to the out-patient department for analyses of the blood made under what roughly approximated home or routine conditions (figures 1, 2, 4, 5). It should be pointed out that the method for blood sugar* used in the out-

* Analyses are done on unaltered blood filtrates⁵ by the Somogyi modification¹⁷ of the Shaffer-Hartmann method¹⁸

patient department gives values for normal (60 to 90 milligrams per 100 c c) which are somewhat below those obtained by the customary Folin-Wu procedure. Nevertheless, the levels at which some of these blood sugars were found are disconcertingly low. The patient J L (figure 4), for example, walked into the clinic one morning feeling perfectly well with a blood sugar of 26 milligrams per 100 c c. While the effect of prolonged, sub-clinical hypoglycemia in the human is not known with certainty, there exists the distinct possibility that functional derangement or even structural damage to tissues may result.¹⁹ Wilder states that he is informed of one death following the use of protamine insulin. When a patient is discharged from the hospital using regular insulin, the increased tolerance for carbohydrate incident to resumption of normal activity causes but little concern with regard to the possible development of hypoglycemia, for the appearance of symptoms is a reliable guide to dosage. With protamine insulin, however, the patient is often deprived of a valuable warning signal, and the only indication of danger may be a laboratory report. It is therefore important that patients who have been sent home taking protamine insulin be requested to return to the office or clinic on two or three occasions when the urine is known to be sugar free for analysis of the blood for dextrose. Since hypoglycemia is most apt to occur in the early morning, this precaution is especially to be observed when the urine specimen passed on arising does not reduce copper.

Others^{18, 19} have directed attention to the difference in symptomatology between reactions due to regular insulin and those due to the protamine compound. Wilder has pointed out that in the case of the latter, the relative lack of perspiration, tremor and palpitation, and the common presence of headache, drowsiness, weakness and sometimes nausea and vomiting may give the impression of acidosis rather than hypoglycemia. The patient must be warned of these differences and instructed to test the urine when in doubt. Paresthesia is a common manifestation. Another peculiarity is that patients who are in unrecognized hypoglycemia may suddenly be precipitated into unconsciousness by a little unusual exertion. The tendency of symptoms to recur after being relieved by carbohydrate has been remarked by a number of observers^{3, 9, 13, 14, 18}

DIFFICULTIES DUE TO DELAY IN APPEARANCE OF FULL EFFECT

Sprague and his colleagues¹⁸ have said of the unmodified protamine insulin, "When using insulin-P, one is aiming about 72 hours ahead." This axiom is even more applicable to protamine-zinc-insulin and is well illustrated by the case of H G (figure 3, Jan 24, 25, 26), in which the blood sugar curve showed progressive improvement over three successive days with no change in the amount of insulin or distribution of carbohydrate, though it was maintained, to be sure, on too low a level. The logical deduction is that changes in dosage should not be too frequent or pronounced.

For the physician schooled in the use of ordinary insulin this is not an easy lesson to learn. The temptation to increase the dose of protamine insulin daily when the patient is excreting sugar is difficult to resist. The lapse of 48 or 72 hours, however, may show that an alteration contemplated earlier would have been not only unnecessary but confusing. It is our belief that many unsatisfactory results, including some of our own, are due to failure to recognize this truth.

The slow and prolonged action of protamine insulin has several disadvantages.

(a) It lengthens the period of stabilization in severe cases. This means additional expense. We have rarely found it possible to reach a satisfactory adjustment with hospitalized patients short of 10 to 14 days, and with outpatients a longer time, with frequent visits, is required.

(b) It renders difficult the transfer to protamine insulin of patients whose tolerance for carbohydrate is rapidly improving, such as those recovering from acidosis, infections and surgical operations.

The patient C. G. (figure 6) for example had been brought out of acidosis and maintained with regular insulin for 10 days after his admission in pre-coma. About the eleventh day (January 8) his tolerance began to improve and the dose of 90 units of regular insulin proved excessive. On January 9, when treatment with protamine insulin was begun, the total dose was accordingly reduced to 80 units (70 of protamine and 10 of regular insulin). This, while apparently satisfactory for the day in question, led to reactions the next, and for the following three days, despite daily reductions in dosage, the patient was in severe, almost constant hypoglycemia due to our inability to estimate the speed at which his insulin requirement was decreasing. Finally no insulin of any kind was given after the injection of 35 units of protamine on the morning of January 12, and not until January 14 did the blood sugar rise appreciably above the normal. On January 15 treatment was resumed with smaller amounts of protamine insulin.

It is probable that in this case the exclusive use of regular insulin, with its relatively short latent period and duration of action, until complete stabilization had been reached would have yielded better results than those obtained by the more prolonged and inflexible action of protamine. On the basis of similar cases we are now reluctant to transfer a patient to the new insulin until a definite plateau of tolerance has been attained with ordinary insulin. Again, it is important to recognize that, with patients who require more than 20 or 30 units daily, this means either extended hospital care over a single period of time or rehospitalization for the express purpose of making the transfer after tolerance has become established under management at home.

Ioslin¹ has stated that the regulation of a previously untreated diabetic with protamine insulin is a much simpler matter. Our experience with this procedure has been limited but encouraging.

(c) Protamine insulin theoretically is disadvantageous in diabetic emergencies such as coma, infection, childbirth and operations. In all these the

condition of the patient is subject to rapid fluctuations against which a quickly acting, easily variable insulin would seem to be the weapon of choice. Exceptions to this view would be emergencies arising in patients already under treatment with protamine insulin. In such cases, as suggested by Colwell⁴ and implied in the report of Kepley, Ingham and Crisler,¹⁰ it may be wise to continue the basic dose of protamine insulin, supplementing it by regular insulin. The employment of the two kinds of insulin in cases of acidosis in which the protamine compound has not previously been used has been reported favorably in a few instances,^{10, 19} but the question of whether this unnecessarily complicates treatment cannot be answered finally without further experience.

(d) The prolonged effect of protamine insulin may, under certain circumstances, involve difficulty of yet another sort. If once a day's supply has been injected under the skin, a sudden illness should prevent the taking or retaining of food, serious hypoglycemia would be likely to ensue unless dextrose were administered parenterally at intervals for 24 hours or longer. One case of this kind has been brought to our attention.

ALLERGY

Three patients in this series developed red, raised, itching lesions at the sites of injection a few days after starting treatment with protamine insulin. One of these had taken ordinary insulin irregularly at home without urticarial reactions. The other two had never received insulin of any sort. In each case the local allergy disappeared spontaneously within a week or two despite continuance of the injections. Joslin⁹ mentions two similar cases not observed by him.

GENERAL PRINCIPLES GOVERNING THE USE OF PROTAMINE INSULIN

Although the treatment of patients with protamine insulin is a highly individual matter, the combined experience of a number of investigators permits the establishment of certain general principles which at least for the present should govern its use. These can best be discussed as applying to two classes of patients.

I *Patients Who Should Begin the Use of Protamine Insulin Only in the Hospital*. This class includes all children, and those adults whose disease is severe or complicated, who are unstable and who live so far from a laboratory that determinations of the blood sugar are not feasible. These patients fall into two groups.

(a) Those who have not received insulin of any sort. Such patients may be treated either by (1) starting the administration of protamine insulin at once, with or without supplementary doses of regular insulin, or by (2) stabilizing the patient entirely with regular insulin and then transferring to protamine insulin.

Although in a few cases reported by other writers^{10, 11} coma has been treated with protamine insulin alone, it would seem safer for the time being to manage all previously untreated cases with severe acidosis, infection or surgical complications by means of regular insulin only. The transfer to protamine insulin should be made as outlined in (b) below and only after a definite plateau of tolerance has been reached.

The other patients in this group may be given protamine insulin uninterruptedly from the time of admission. The dietary carbohydrate should as a rule be apportioned $\frac{1}{5}$ for breakfast, $\frac{2}{5}$ for lunch and $\frac{2}{5}$ for supper. A single injection of protamine insulin, the amount determined by an "educated guess," is given each morning an hour before breakfast, supplemented if necessary by a smaller dose of regular insulin at the same time. Although some authors⁸ have found it permissible to give the two kinds of insulin simultaneously in the same syringe, the majority agree that this procedure leads to the precipitation of a certain and probably variable portion of the regular insulin by the protamine present and tends to yield inconstant results. The same syringe may be used provided that the regular insulin be withdrawn and injected first, but the sites of injection should be separate. Specimens of the urine and, if possible, the blood, are obtained on arising and three hours after each meal and examined for sugar. Unless grossly inadequate the dose of protamine insulin should not be changed before three or four days or more have elapsed. As improvement occurs the regular insulin may be reduced and finally omitted, although in some cases its permanent use is necessary. Further rearrangement of carbohydrate should be made as indicated. The safest and best guide to the proper amount of protamine insulin is the level of the blood sugar in the early morning. In order to allow for the effect of increased activity at home, it is a wise precaution to discharge hospital patients with a dose which permits slight hyperglycemia.

(b) Those who are already receiving regular insulin. In these cases it is usually best to begin with an amount of protamine equal to the total daily requirement of regular insulin. For the first few days, at least, glycosuria is better controlled by giving simultaneously but in a different site a dose of regular insulin equal to from one-third to one-fourth of this amount. The regular insulin may be in addition to the protamine used, or may be substituted for an equal quantity of the latter, depending on the case. In most instances it is possible to decrease the dose of regular insulin a few units at a time over a period of three or four days until finally protamine insulin alone is given.

II *Patients Who Can Safely Begin the Use of Protamine Insulin in the Office or Out-Patient Department*. These patients are adults whose disease is uncomplicated and of only moderate severity, who give promise of being fairly stable and who live within convenient distance from a laboratory. They also fall into two groups.

(a) Those who have not received insulin of any sort Joslin^{7,8} emphasizes the safety, simplicity and wide applicability of using only protamine insulin in such cases. A patient of this type, *provided he shows no ketosis*, should be given a diet, weighed if possible, with the carbohydrate divided $\frac{1}{5}$ for breakfast, $\frac{2}{5}$ for lunch and $\frac{2}{5}$ for supper, and should be taught the technic of urinalysis, tests being made on arising and about three hours after each meal. Having been instructed in the method of administration, he should be told to take one hour before breakfast a dose about one-third less than that which, on the basis of experience, the physician thinks may be his requirement. This dose should not be changed for the next three or four days, the patient meanwhile testing the urine as described and communicating the results to his doctor daily. It is far better to start with a relatively small dose of protamine insulin and permit glycosuria for a few days than to begin with too large a dose which may, in 48 or 72 hours, produce hypoglycemia in the early morning. The dose can be increased more easily than it can be reduced. Subsequent changes in dosage should not be made daily. When the urine tends to become sugar free, and particularly if the specimen on arising is clear, a determination of the fasting blood sugar should be made, or if this is impossible the dose should be reduced a few units every three or four days until sugar reappears in the urine, then raised a notch. If hypoglycemia does develop, the dose should be promptly dropped to a level calculated to result in glycosuria and again be built up gradually. By this time further adjustments in carbohydrate distribution as described earlier may be necessary, including possibly a bed-time feeding. If any unusual difficulties are encountered the patient should be hospitalized.

(b) Those who are already receiving small or moderate amounts of regular insulin. It is our belief that in this group only the patients who are comparatively stable and who require not more than 20 or at the most 30 units daily should be transferred to protamine insulin outside the hospital.* Since the supervision of ambulatory patients cannot be so close as that of hospital patients, the initial dose of protamine insulin should be equal to only about two-thirds of the previous total daily requirement, the other third, more or less, being given as regular insulin. The next day half the amount of regular insulin, or possibly none at all, depending on the urine tests, may be given. Further adjustment of diet and insulin may be made as outlined in the preceding paragraphs.

Because the hypoglycemia produced by protamine insulin is so commonly asymptomatic, the importance of making frequent determinations of the blood sugar, both during the period of adjustment and after the patient has gone home, cannot be overemphasized.

* Richardson and Bowie¹⁴ using unmodified protamine insulin, have reported the out-patient transfer of over 30 patients whose requirements were less than 40 units daily.

SOME OF THE PRACTICAL PROBLEMS IN THE SERUM THERAPY OF BACTERIAL INFECTIONS

By AUGUSTUS WADSWORTH, *Albany, N Y*

SERUM therapy is an outgrowth of the discovery that microorganisms, the bacteria, are incitants of infectious disease. As such, it is difficult to differentiate the results of the branch from those of the parent stem. For example, in diphtheria, early diagnosis with prompt isolation has alone had a far-reaching effect not only upon the morbidity but also, indirectly, upon the severity of the disease, and it is difficult to distinguish the effect of the discovery of the diphtheria bacillus and of improved public health methods from that of the specific treatment with antitoxin, on the morbidity and mortality of the disease. Much of the decline is to be attributed to advancing medical science, apart from specific serum therapy, as exemplified in the diminishing morbidity and mortality of other infectious diseases. Much of the lowered mortality of diphtheria, however, may be accredited to treatment with antitoxin, and these results have reached an astounding magnitude when measured in terms of human happiness and welfare.

Forty years' experience with diphtheria antitoxin illustrates very strikingly the major problems of serum therapy. In some respects they may vary according to the disease and its bacterial incitant, in others, they do not differ materially. These problems may be classified under two main headings: one, the preparation of potent, effective sera in the laboratory, the other, early treatment with adequate dosage at the bedside. Preparation of diphtheria antitoxin has advanced steadily. There has been marked improvement as evidenced by a more than tenfold reduction in dosage and an even greater increase in potency. No one now criticizes the quality or questions the potency of the diphtheria antitoxins that are distributed under governmental supervision and control. Corresponding reduction in mortality at first paralleled the improvement in antitoxin, but there is now a residual mortality that eludes even this specific therapy. The residual mortality in diphtheria is now to be attributed to delayed treatment or inadequate dosage, possibly entirely to delayed treatment. It would be important from a public health standpoint to have complete information regarding every fatal case of diphtheria.

Effective serum therapy depends primarily upon the neutralization of toxic substances, secondarily, upon the destruction of the bacterial incitant.

* Received for publication July 15, 1937.

From the Division of Laboratories and Research, New York State Department of Health, Albany.

The extent to which one process is dependent upon the other, as well as the precise sequence of events in the different infectious diseases, offers a most important field for investigation. Unfolding knowledge of group and type specificity reveals the subtle interrelationships of the antitoxic and antibacterial activities of serum in relation to the protective mechanism of the tissues of the host that underlie effective serum therapy.

The antitoxic action of serum therapy has been contrasted very sharply with the antibacterial phenomena attributed to the sera that are used in the specific treatment of infectious diseases, the bacterial incitants of which invade the tissues generally. So sharply have these two activities been differentiated that the antitoxic action of the antibacterial sera has been overshadowed. In the laboratory, studying the different activities or manifestations of immune sera, it is important to classify and differentiate sharply, but when one turns to the study of effective serum therapy in the infectious processes of the tissues, it is not only difficult but unwise to differentiate these activities.

Sera differ in their antitoxic and in their antibacterial action, but just how they differ and to what extent, or how they are interdependent and to what extent, is of paramount concern to us all since these relationships underlie all phases of vaccine and serum therapy. The type specificity of botulinus antitoxin on the one hand, and on the other, the type specificity of the anti-pneumococcus sera represent extremes.

Antitoxic serum exerts an antibacterial effect, possibly directly, but more obviously indirectly upon the incitant of infection in the tissues. The diphtheria, tetanus, and botulinus antitoxins are the most representative. With diphtheria and tetanus infections, group and type specificity are not involved, despite the fact that strains of these microorganisms vary widely in their toxigenicity and antigenicity, not that the diphtheria bacillus may not be divided into subgroups on the basis of selected characters, but that the toxin produced by the different strains has invariably been neutralized by the standard antitoxin. In diphtheria, the administration of antitoxin neutralizes the toxin and crisis occurs promptly. Following this, the diphtheria bacilli are destroyed by the protective mechanism of the tissues unless these bacilli are so situated that they evade the action of the tissues and survive as relatively harmless parasites in the carrier state. However, when the disease has progressed to a later stage, the tissues are vitally injured. Neutralization of the free toxin by antitoxin is inadequate and the protective mechanism fails to destroy the diphtheria bacilli. These examples of the simplest form of serum therapy very strikingly illustrate its fundamental limitations. Tetanus antitoxin acts similarly. The tetanus bacillus, however, is less readily established as a parasite in the tissues when its toxic activity ceases to injure the tissues. Recovery, when it occurs, is complete in that the incitant does not persist as a parasite in the tissues. Although group or type specificity does not figure in serum therapy of tetanus or diphtheria infections, the toxigenicity and antigenicity of different strains

of these microorganisms are most important factors in the production of potent antitoxins

With the incitants of botulism, which is also a simple toxemia without invasion of the tissues by the incitant, type specificity plays an important rôle in serum therapy because the neutralization of the toxins in the test tube as well as in the tissues depends upon the homologous relation between the incitant and the antitoxin that is used in serum therapy. Thus, the antitoxin of A, of B, and of C microorganisms is effective only in the corresponding infections of A, of B, and of C types. The limitations of serum therapy, as illustrated by the above cited examples of diphtheria infection, are even more sharply defined in botulism. To be effective, an antitoxin must be administered almost immediately. The crisis of the disease process, irrespective of serum therapy, occurs promptly because the disease is so largely a toxemia and practically uncomplicated by even a localized infectious process. In fact, the majority of the cases are simply the absorption of a large amount of toxin. The crisis occurs so promptly that the patient either dies or recovers irrespective of the administration of serum. Nevertheless, the antitoxin should be given because, after all, it is impossible to determine by any clinical signs whether the crisis has been reached or passed.

An antitoxic serum exerts an antibacterial effect when it is used in the treatment of an infectious process the incitant of which is localized, and the disease largely, if not entirely, toxic in character. Moreover, antibacterial sera exert an antitoxic effect either directly or indirectly upon the incitant of the more generalized infectious diseases. The antipneumococcus and antimeningococcus sera are representative examples of antibacterial sera. Antipneumococcus serum exerts definitely specific action, sharply defined according to the type specificity which is related to the carbohydrates of the microorganisms. The direct antibacterial action is well recognized and is evident in the protection test in mice and the effect of the serum on phagocytosis.

In the absence of demonstrable toxin, it is difficult to obtain evidence of an indirect antibacterial action associated with an antitoxic activity that conserves the tissues and favors the destruction of the pneumococci by the protective mechanism that follows neutralization of the toxin. However, the antitoxic action is manifested by the critical effect of the serum on the febrile reaction of pneumonia corresponding to the crisis that occurs spontaneously. The neutralization of the toxin may precede or follow the destruction or inhibition of the pneumococci in the tissues. However, following neutralization of its toxic activity, the pneumococcus may persist as a parasite relatively harmless to its host, as evidenced by survival of the pneumococcus after the crisis of pneumonia, and in the highly immunized animal when it becomes attenuated and its toxic activity nil. The virulence of these pneumococci is lost, they are no longer toxic but continue as parasites¹. Thus it is that the antibacterial antipneumococcus serum doubtless

exerts an antitoxic as well as an antibacterial effect when it is used in the treatment of pneumonia

The antimeningococcus serum also, quite similarly, exerts a definite and specific effect. The antitoxic activity of this serum is, at present, stressed. As in pneumonia, there has always been clinical evidence that the serum exerted a marked antitoxic as well as antibacterial effect. On account of the general insusceptibility of laboratory animals to infection, it has been and is difficult to differentiate the antitoxic and antibacterial action of antimeningococcus serum. However, results of protection tests in mice²⁻⁵ with cultures suspended in mucin do distinguish different degrees of activity in different sera. The intracutaneous test⁶ and protection tests against lethal doses of toxic extracts or filtrates in animals⁷⁻¹³ are not yet of practical value in the titration of antitoxic potency.

Antistreptococcus sera exert definite and specific antitoxic and antibacterial effects in the treatment of infection. The specific relationship is marked and complicated with the streptococci because it relates not only to the antitoxic activities of the serum and the antigenic activity of the toxins in producing the antitoxic serum,^{14, 15} but also to the antibacterial activity of the serum as it is manifest in the protection test¹⁶⁻¹⁹. The study of antistreptococcus serum, even in its present elementary stage, has revealed the most striking and convincing demonstration of how essential are the antitoxic, as well as the antibacterial activities of the serum to an effective serum therapy of streptococcus infection as soon as it has become generalized. In the earliest stages of certain infections, the antitoxic activities^{20, 21} may suffice as they do in diphtheria. The direct antitoxic effect in neutralizing the toxin and the indirect antibacterial effect by favoring the protective mechanism of the tissues suffice to determine recovery—possibly with or even without any direct antibacterial action of the serum. In all these actions and reactions, however, the homologous relations are important on account of the marked type and toxin specificity manifested by the different hemolytic streptococci.

Although specificity of the toxins is well marked, it has no relation to the disease processes incited by the hemolytic streptococci—scarlet fever, erysipelas, puerperal fever, etc. No specific etiological relationship has as yet been established. The toxic activities of the different strains vary greatly not only in potency but in character. Similarly, the antigenic potency and valency also vary with the strain and irrespective of the toxin group, specificity, or titer of the toxins.

The antitoxic activities of the serum thus accordingly vary^{15, 22-26}. Within a group the potency of serum produced with one strain may be high and the valency narrow, whereas in that produced with another strain, the converse may obtain. Although in general the neutralization of the toxin takes place in the homologous relation according to groups, the potencies and valencies of the different antitoxic sera vary widely. Combination of representative sera may broaden the valency beyond that manifested by either

serum separately. As a result of the study of more than 1500 cultures, two strains have been selected with which, in combination, it has been possible to obtain an antitoxic serum of such broad valency that the toxins of all strains encountered thus far are neutralized. Finally, and what is of the utmost importance, qualities may be supplied by the tissues of the animal host, which doubtless account in large measure for the manifestations of the antitoxic as well as the antibacterial effect of heterologous sera in infectious processes whether studied clinically in the treatment of human infection or experimentally in animals.

Factors which further complicate the problem of effective serum therapy with all of these bacteria are differences in the cellular susceptibilities of the microorganisms themselves as well as the activities of the tissues in their presence. For example, the biologic stability and also, so to speak, the fragility of the pneumococcus cell in disease processes, together with its capacity for adaptation, are determining factors in the serum therapy of pneumonia as they are in the prognosis of the untreated disease.

The thermal limits of growth, depending upon the strain and a favorable environment, vary with the pneumococci from 39°C to about 41°C ^{27, 28}. In immune serum, the pneumococcus cell vegetates at 37°C . At temperatures above the thermal limits of growth, varying degrees of lysis may take place. Hyperthermy, experimental elevation of body temperature, may inhibit, or even eliminate temporarily, the pneumococcemia of some infections in susceptible animals, whereas it may hasten the course of others ²⁹. Treatment with immune serum induces crisis in the febrile reactions, there is neutralization of the toxemia and marked destruction of the bacteria. The pneumococcus cell is fragile, and especially so if compared with the streptococcus, although the thermal limits of growth of many strains of hemolytic streptococci do not exceed materially those of some of the pneumococci ²⁷. Immune serum in streptococcus infection may induce pseudo crises in the febrile reaction without affecting to a corresponding degree the bacteremia which may, and often does, progress. The streptococci, moreover, produce a toxin, and, like strains of the diphtheria bacillus, vary greatly in this respect. Certainly the quantities produced by some of the streptococcus strains can scarcely be recognized experimentally, yet when these streptococci invade the tissues of a host, the febrile reaction induced is convincing proof of their toxigenic capacity. The toxin of the pneumococcus, when this microorganism is cultivated *in vitro*, has not been recognized, yet the febrile reaction of pneumonia is convincing proof of the toxigenic activity of this incitant of infection. The pneumococcus is toxigenic when developing in an animal host but not under ordinary experimental conditions *in vitro*. Effective antibacterial sera in the treatment of pneumococcus and meningococcus infections are produced by the immunization of horses with living virulent cultures. Moreover, antitoxic streptococcus sera of the highest potency, in my experience, can only be obtained with living cultures and as a

result of the development of the streptococci in the horses undergoing immunization

Evidence of wide variation in the subtle cellular susceptibilities of the bacterial incitants of infection accumulates when the toxigenic and antigenic activities are studied for the purpose of preparing therapeutic sera of high potency and broad valency. The criteria for the selection of cultures for antitoxin are sharply defined: a potent toxin of high antigenic value must be produced. The vicissitudes of maintaining, not to mention developing, diphtheria strains for antitoxin production during the past 40 years are well known. Even more convincing is recent experience with the selection of strains of the hemolytic streptococci for the preparation of therapeutic serum. The same criteria in use for the diphtheria cultures must be fulfilled, and, in addition, there must be taken into account qualitative as well as quantitative differences in the kind of toxin produced in relation to its antigenic activity.

The criteria for the selection of cultures for production of the so-called antibacterial sera are not so sharply defined, apart from the empirical test of producing potent therapeutic serum. For the pneumococci, virulence and possibly carbohydrate production are practically the only guides. For the meningococcus, until very recently, the agglutination reaction has been one of the most valuable aids because the valence and antigenicity can be determined within the limitations of the significance of this reaction³⁰⁻³². The precipitation reaction,³³⁻³⁵ the virulence test with mucin in mice,² and several tests of toxic activity^{6, 8, 36-38} are now available to demonstrate comparative differences in strains. It still remains, however, to correlate these various activities of the culture with its efficacy in the production of potent therapeutic sera. The selection of freshly isolated strains has been stressed, but these strains vary, and it is perhaps far more important to select stable representative strains of proved high antigenic potency and broad antigenic valency and, as is now practicable, to maintain their biologic status^{2, 3, 31, 32, 34, 39-41}.

An immediate practical problem concerns the value of concentration or separation of the active globulins of antitoxic and antibacterial sera. In addition to economic considerations, there is the question as to whether or not the loss which concentration entails is due entirely to the failure to recover all of the active substances or whether certain supplementary or complementary activities of the sera are eliminated. Certainly it is not conceivable that there is a gain in therapeutic value save as the result of elimination of extraneous protein which may have a deleterious action as evidenced by the greater proportion of serum reactions with the unconcentrated serum as compared with the concentrated. However this may be, the concentration of diphtheria antitoxin, for example, has become an established procedure. Moreover, physicians at the bedside will invariably administer refined preparations in preference to the untreated serum. Concentration as it relates to the preparation of the antipneumococcus, anti-

meningococcus, and antistreptococcus sera, has only recently been adopted. It has, however, become essential from a practical point of view. Experience with the concentrated as compared with the unconcentrated products is limited to a comparatively short period. Moreover, during the past decade there has been a marked improvement, as a result of experience in their preparation, in the therapeutic value of all of these sera generally available. The potency has been materially advanced and the valency broadened. The data and statistics are, therefore, not generally comparable—quite apart from the variations in the severity of the infections treated with the different sera. I therefore do not feel competent to evaluate the reports of other observers and have been forced to rely upon personal experience with the sera prepared in our laboratory during this period. Fortunately some direct comparisons are possible from the data that have been collected through the kindness of Dr. Cole of the Rockefeller Hospital and of Professor Longcope and Professor Park of Johns Hopkins Hospital, who have had opportunities of comparing the unconcentrated and the concentrated sera prepared by identical methods and of equivalent potencies and valencies. These data I consider reliable.

During the short period that the sera have been refined by special methods,⁴²⁻⁴⁴ 25 cases of type-I pneumonia have been reported by Dr. Abernethy from the Rockefeller Hospital⁴⁵, three more may now be added to this series in which no fatalities have occurred. In an earlier series of 371 cases treated with unconcentrated serum, Cole reported a mortality of 10.5 per cent.⁴⁶ The results in these two series, however, are not strictly comparable. In those cases treated with the concentrated serum the Neufeld technic was available. The prompt type diagnosis thus provided accounts for an earlier administration of serum, and under these improved conditions of treatment a lower mortality may well follow. In 89 cases of meningococcus meningitis treated at Johns Hopkins Hospital with the concentrated product alone, there were 8 deaths (8.9 per cent). In 31 cases which were given both concentrated and unconcentrated serum, there were 3 fatalities (9.7 per cent). During the same period, 32 patients were treated with the unconcentrated serum with 4 deaths (12.5 per cent). In each group the fatal cases included some which had complications of pneumonia or which were moribund when admitted, but survived the first treatment longer than twenty-four hours. Dr. Tillett reported on a group from this series in 1935.⁴⁷ These results cannot be credited wholly to the serum that was used because they may be due quite as much, or even entirely, to early treatment with adequate dosage. Serum reactions were materially diminished with the concentrated preparations. Some reactions, however, have been noted with the concentrated antimeningococcus serum when given intraspinally, although the percentage of protein does not materially exceed that of the untreated serum.

Problems of serum therapy thus relate to the preparation of the serum on the one hand and, on the other, to its administration. The selection of

strains according to their toxigenicity, antigenicity, and valency is of first importance in the preparation of the antibacterial serum as it is with the antitoxic sera, and especially is this true when type specificity is involved. The quality and potency of the diphtheria antitoxins are now no longer questioned. There has been steady improvement in the antibacterial sera during the past ten years. It has been possible to select representative strains of the meningococci, the antigenic potency and valency of which make it possible to prepare effective polyvalent antimeningococcus serum. The antigenic properties of these strains can be maintained in the laboratory so that it is unnecessary to resort to freshly isolated strains, save as a means of replenishing or improving standards.

In the preparation of antipneumococcus serum, the type specificity of the strains as antigens is so marked that it has not been possible to prepare effective polyvalent serum. Early type diagnosis and the administration of the homologous serum are therefore essential.

In the preparation of antistreptococcus serum, not only must the type and toxin specificity of the strains be considered, but also the antigenic action, which varies. A serum of broad valence is essential since early type diagnosis is not practicable as in pneumonia. In the production of antitoxic serum it is now possible by the selection of two strains of hemolytic streptococci to obtain a serum of high potency and a valency so broad that it includes the toxins of practically all strains.

Preparation of all these sera has advanced to the point where it is now necessary to stress particularly the other side of the problem—namely, early diagnosis and early treatment with adequate dosage.

THE COMPARATIVE VALUE AND THE LIMITA- TIONS OF THE TREPHINE AND PUNC- TURE METHODS FOR BIOPSY OF THE STERNAL BONE MARROW

By WILLIAM DAMESHEK, M D , HENRY H HENSTELL, M D ,[†] and
ELEANOR H VALENTINE, M D , *Boston, Massachusetts*

THE last few years have witnessed a striking development of interest in the sternal bone-marrow biopsy. This is undoubtedly due to at least two factors: the rapidly increasing interest in hematology which followed the discovery of the value of liver in pernicious anemia, and the increasing recognition that the so-called "blood diseases" are in reality disorders of the blood-forming organs, more particularly of the bone-marrow. Biopsy of the sternal marrow, introduced by Seyfarth¹ in 1923, rapidly displaced the much more difficult biopsy of the tibia which was practised by Zadek,² Peabody,³ and a few others. The diagnostic value of the sternal bone-marrow biopsy particularly in cases presenting anemia, leukopenia, and thrombocytopenia has already been referred to in another paper.⁴ The technic of the procedure consists in brief of the removal by trephine of a small plug of bone from the sternum. Two types of preparations are obtained: (1) *sections*, made by imbedding and cutting the small plug of bone removed, and (2) *smears*, made by touching gently bits of bone removed by curette from the trephine cavity. In the above paper and in another describing the appearance of the bone-marrow at biopsy in pernicious anemia,⁵ the important features of both types of preparation were stressed, i.e. from the sections are obtained general ideas of the cellularity of the marrow, the topographical relations of various groups of cells, and the presence or absence of islands of embryonic cells. From the smears, careful study of the individual cells can be made, the cells appearing much as in a blood smear without the distortion and shrinkage frequently found in the sections. The definite impression has been obtained that in order to make a proper study of the sternal bone-marrow at biopsy, both the marrow sections and smears are essential, each type of preparation having its definite shortcomings and advantages.

* Read before the American Medical Association, Section on Pathology and Physiology, June 9, 1937. From the Medical Service and Hematology Laboratory, Beth Israel Hospital, Boston. Written in honor of the Festschrift of Dr. Joseph H. Pratt who has been keenly interested in the development of the bone-marrow biopsy and whose encouragement made some of the early studies possible.

Aided by a grant from the Charlton Fund, Tufts College Medical School.

[†] Charlton Research Fellow, Tufts College Medical School.

More recently another method for examining the sternal marrow has been introduced. In this method, a modified lumbar puncture needle is plunged into the sternal cavity and material obtained for smears by suctioning with a syringe. First introduced by Arinkin⁶ and other Russian investigators, the method became widely practised, so much so that within the last few years two monographs (Segerdahl,⁷ Nordenson⁸) have appeared based entirely on this procedure. A large number of articles extolling the ease of technic and the diagnostic value of the method have appeared.⁹ As far as we know, there has been no critical appraisal of this method nor any comparison of the results with those obtained by the trephine method. The present paper, which deals with a critical examination of these questions, is based upon a comparison of the data obtained by both methods in 20 consecutive cases, together with a review of the pertinent data from about 200 previous biopsies.

METHODS

Under aseptic precautions and following thorough infiltration of the skin and periosteum with novocaine, a small incision 1 to 2 cm in length was made over the midsternum in the region of the fourth intercostal space. The periosteum was exposed, incised, and retracted in the ordinary manner. A puncture diagonally through the anterior lamella of the sternum was then made with a lumbar puncture needle which had been shortened to about one-half its regular size. When a sensation of "give" was obtained, the stilet was removed, and a very small quantity of material aspirated into a 20 c.c. syringe. Ordinarily, less than 0.5 c.c. of material was removed and this was spread gently on glass slides as with blood smears. Following this puncture, a small trephine was introduced into the sternum and a small plug of bone removed. This was immediately placed in Zenker's solution containing 5 per cent of glacial acetic acid sufficient for decalcification. The cavity resulting from the removal of the plug of bone was carefully scraped with a fine curette, bits of bone being removed which were then gently smeared on glass slides. Reticulocyte preparations were made with both the puncture and trephine preparations by using slides which had previously been coated with a thin film of cresyl blue (0.3 per cent brilliant cresyl blue in 95 per cent alcohol). Both types of smears were stained either with Wright's stain or with Giemsa stain and in several instances a combination of both stains was used. The Wright's stained preparations gave uniform results and presented delicate cellular pictures. The Giemsa stained preparations were more "brilliant" and showed better staining of the granules, although the nuclei were at times overstained. Differential counts of the "puncture" and the "trephine" smears were made, in both cases at least 500 cells being counted. Reticulocyte counts were made in most instances, 1000 non-nucleated erythrocytes being counted. The sections, after ap-

propriate fixation, were prepared in the ordinary way with paraffin and stained with eosin-methylene blue *

STERNAL BONE MARROW BIOPSY
Trepine vs Puncture Method

| | Trepine | Puncture |
|----------------------------------|--|---|
| 1 The Smears—General Exam | Normally highly cellular | Frequently very few marrow cells |
| 2 Ratio Nucleated R B C to W B C | About 1 : 1 | Usually about 0.5 : 1 |
| 3 Types of Nucleated R B C | All types, including most primitive, present | Primitive cells much diminished, often absent |
| 4 Reticulocytes | 5-15% | 0.5-2% |
| 5 W B C | Essentially similar findings | _____ |
| 6 Megakaryocytes | Common | Infrequent |
| 7 Ease of Performance | Relatively difficult | Easy—Amassing of data Serial observations Children |
| 8 Interpretation | Relatively easy, because both sections and smears obtained | Smears only, often with more blood than marrow, make interpretation difficult |

The morphological characteristics of the various cells encountered in the marrow have already been described in previous papers. All cells were carefully studied from the standpoints of size, shape, cytoplasmic characteristics (amount, color, granules, vacuoles) and nuclear characteristics (size relative to cell, type of nuclear chromatin, nucleoli). The leukocytic cells discriminated were the histiocyte (hemohistioblast), myeloblast, promyelocyte, myelocyte, metamyelocyte, mature polymorphonuclear cell, eosinophile and basophile. Our nomenclature for the erythroblastic cells is based on previous studies in pernicious anemia and differs somewhat from that of other authors. The most primitive cell of this series is the erythrogon, which is found in all conditions in which the marrow is hyperplastic and is apparently the forerunner of both the megaloblast and the normoblast. In the absence of "liver extract substance" (pernicious anemia and related states), an abnormal or megaloblastic type of erythropoiesis takes place. Various grades of maturity of megaloblasts are seen and these may be arbitrarily classified as "A," "B," and "C."

When "liver substance" is present, normal red blood cells are formed, i.e. *normoblasts*. Similarly, three types of normoblasts are distinguished "A," "B," and "C," corresponding to the terms frequently used in the literature of macroblast, erythroblast, and normoblast respectively.

RESULTS

A The Smears Differential counts from both types of preparations in 20 cases together with the ratio of nucleated red blood cells to white blood

* Best results in staining both smears and sections were obtained by using the Gruebler stains

5

cells, and the reticulocyte counts are presented in table 1. In three cases, the "puncture" smears were very poor in cells, making differential counting difficult if not impossible. This has frequently been our experience in other cases when only puncture was done and the same is noted in many of the protocols of both Nordenson⁸ and Segerdahl.⁷ In the "trephine" preparations, except in those cases with an acellular marrow, highly cellular preparations were always obtained. In the "puncture" preparations, the cells obviously arising from the marrow were relatively scanty as compared with the numbers of mature erythrocytes in the preparations, so that the picture usually resembled closely a blood smear either from a case showing leukocytosis or leukemia. Differential counting in these preparations was at times somewhat easier than in the "trephine" preparations in which the cells might be closely packed together, but one obtained the definite impression that in the one case one was dealing with blood containing a few marrow cells whereas in the other one dealt with marrow interspersed with some blood cells.

Ratio of Nucleated Red Blood Cells to White Blood Cells This ratio, which from previous studies had generally been found to be about 1 to 1 (with variations from 0.6 to 1 to about 1.5 to 1) is useful in estimating whether the granulocytic or erythroblastic cells predominate in a given preparation. It may be seen from the table that, although the ratio of red cells to whites was frequently substantially the same in both types of preparation (Cases 4, 5, 6, 11, 13, 16), in 14 cases it was different. In each of these cases, the ratio of nucleated red cells to white cells was definitely less in the puncture preparations. In several cases, the preponderance of white cells to reds in the puncture preparations was quite striking (3, 7, 8, 10, 14, 15, 18). These findings may be interpreted as signifying the failure of the primitive red cells to appear in large number in the "puncture" smears as noted below.

From table 1, one sees that in seven of the 20 cases, the most immature nucleated red cells (erythrogones, megaloblasts, normoblasts "A," "B") in the "trephine" preparations far outnumbered the same types of cells in the puncture preparations. In several cases the results obtained in the "puncture" preparations might well have been misleading in this regard. In Case 3, for example (pernicious anemia), megaloblasts were present in

-

- 1b Smear. Made from puncture biopsy in same case. Note the scarcity of marrow cells and the large number of blood cells. $\times 500$
- 2 Trephine biopsy. Smear. Various types of nucleated red cells are seen. The smears are invaluable for study of individual cellular morphology. $\times 1000$
- 3 Trephine biopsy. Smear. Various types of granulocytes are seen. $\times 1000$
- 4 Trephine biopsy. Section. Polycythemia illustrating marked hyperplasia of megakaryocytes. Megakaryocytes are found only occasionally in puncture preparations. $\times 550$
- 5 Trephine biopsy. Section. Aleukemic reticulosis. The marrow is replaced by dense tissue. Smear preparations were worthless since they showed no cells. $\times 125$

6

7

8a

8b

9a

9b

fair number in the trephine preparations and almost completely absent from the puncture preparations

Reticulocyte Percentage This was used as an index in demonstrating the relative maturity of the non-nucleated red cells in the trephine as compared with the puncture preparations and was determined in 11 cases. In nine of these the percentage of reticulocytes was greater in the trephine preparations, although in two cases (9 and 11), both of them examples of pernicious anemia under treatment, the reticulocyte per cent was greater in the puncture preparations

White Cells Although rather marked differences in the percentage composition of the white cells were present at times, no such striking disproportion between immature and mature leukocytes as existed with the erythroblastic cells could be seen, although in two cases (4 and 6) the percentage of myeloblasts in the trephine preparations was much higher than in the puncture preparations

Megakaryocytes These huge cells were commonly found in the trephine preparations, being seen only occasionally in the puncture preparations

B The Sections These were of course present only with biopsy preparations. Although artificial sections may be prepared from the puncture preparations by allowing the puncture material to clot and then sectioning it in the ordinary way, these were not made. As brought out in previous papers,^{4, 5} the sections are of value not so much for the examination and study of the individual cells as for the study of the topography of the marrow and its general functional state (hyperplasia, hypoplasia, etc.), the recognition of islands of proliferating leukemic or malignant cells, the relationship of islands of cells to each other and to adjoining reticulo-endothelial cells and for study of the megakaryocytes

Smear preparations, particularly those obtained by puncture, may show varying degrees of cellularity dependent wholly upon differences in technic. These differences may be so great that the distinction between hypoplasia and hyperplasia may be impossible. Thus, in Case 17 (benzol poisoning), the smears from both the biopsy and puncture preparations seemed to show an essentially normal number of cells, and yet the sections (figure 10) showed a striking degree of hypoplasia of most of the marrow with small islands of fairly normal cellularity. In Cases Mary C, Mitchell G, Edna S, Charles

FIG 2 6 Trephine biopsy Section Lymphosarcoma of spleen, metastasis to bone-marrow with fibrous tissue replacement. The smear preparations showed no cells. $\times 500$

7 Trephine biopsy Section Lymphosarcoma, metastasis to bone-marrow. Dense mass of tumor tissue present in one small area of section, not discovered in smear preparations. $\times 300$

8a Trephine biopsy Section Metastatic carcinoma of pancreas. Bone-marrow replaced by fibrous tissue. No malignant cells seen. $\times 300$

8b Trephine biopsy Smear The smears (same case as 8a) showed groups of primitive cells thought to be carcinoma. This was later confirmed by post-mortem examination. $\times 1000$

9a Puncture biopsy Smear Splenomegaly? cause Smears showed normal marrow cells with a rare large cell called a histiocyte. $\times 1000$

9b Trephine biopsy, same case Smear Large numbers of Gaucher cells present in the smears and sections making diagnosis readily possible. $\times 1000$

TABLE II
Smears and Sections

| | Smear Preparations | Sections |
|------------|---|--|
| Mary C | Diminished cellularity | Islands of leukemic cells |
| Mitchell G | No cells | Connective tissue replacement of marrow (lymphosarcomatosis) |
| Edna S | No cells | Aplasia of marrow |
| Charles M | Very few cells | Replacement of marrow by reticulum and connective and proliferating reticulum cells with giant cells (aleukemic reticulosis) |
| Eva S | Very few cells | Small localized area of lymphoblastic proliferation (lymphosarcoma) |
| Jacob H | Very few cells ? Islands of abnormal cells | Metastatic malignancy (carcinoma of pancreas) with connective tissue replacement of parts of marrow |
| Sylvia W | Hyperplasia of W B C <i>Diagnosis</i> Myeloid leukemia | Cellular bone-marrow ("Banti's disease") |
| Bessie D | <i>Diagnosis</i> Myeloid leukemia (Proliferation with primitive cells) | Hyperplastic bone-marrow, no unrestrained growth, islands of primitive cells surrounded by typical nucleated R B C <i>Diagnosis</i> Pernicious anemia |
| Maria B | Hyperplasia of myeloblasts <i>Tentative Diagnosis</i> Aleukemic myelogenous leukemia | <i>Diagnosis</i> confirmed by sections which showed islands of proliferating myeloblasts with invasion and destruction of R B C and megakaryocytes |
| Isadore L | Normal marrow | Hypoplastic marrow with small areas of normal cellularity No megakaryocytes <i>Diagnosis</i> Hypoplastic anemia (benzol poisoning) |

M, Eva S, Jacob H (table 2), very few marrow cells were found in the smear preparations. All of these cases presented anemia, leukopenia, and thrombocytopenia, and it was impossible to state at the time whether the absence of cells was due to faulty technic or to actual aplasia of the marrow. It was only when the sections were studied in these cases that the true pictures became evident: myeloid leukemia, fibrosis of the marrow following lymphosarcomatous invasion, aplasia, aleukemia reticulosis, lymphosarcoma invading the marrow, carcinomatous invasion, and fibrosis of the marrow.

When dealing on the other hand with an obviously hyperplastic marrow in the smear preparations, it is at times difficult to state definitely whether or not leukemia is present. Occasionally (Cases Sylvia W and Bessie D are illustrative) the diagnosis of myeloid leukemia had been made on the basis of apparently extreme myeloid hyperplasia. The sections, however, in the first case showed normal, although hyperplastic, islands of both red and white cells without destruction or replacement of erythroblastic or mega-

karyocytic elements ("Banti's disease") In Case Bessie D, the very primitive erythroblastic cells present (erythrogones) were mistakenly called myeloblasts, the sections showed islands of primitive cells, at the edges of which were easily recognizable erythroblastic cells i.e. pernicious anemia. However, from sections alone, it is usually difficult if not impossible to distinguish between leukemia and pernicious anemia since both show large islands of primitive cells.

COMMENT

1 *Diagnostic Value of the Sternal Bone-Marrow Biopsy* During the past ten years, ample proof has accumulated of the diagnostic value of the

10

11 a

11 b

11a Trephine biopsy Section Extremely hyperplastic marrow with many primitive cells erroneously diagnosed as myeloid leukemia. $\times 500$

11b Trephine biopsy, same case Smear The smears showed many megaloblastic cells and deformed metamyelocytes typical of pernicious anemia. The smears are essential for study of individual cellular morphology. $\times 1000$

sternal bone-marrow biopsy Its chief use has been in the differential diagnosis of those cases presenting obscure and chronic anemia refractory to liver and iron Usually these cases are associated with leukopenia and thrombocytopenia This triad of hematological findings—anemia, leukopenia, and thrombocytopenia—may be due to many different conditions of the marrow Thus, the marrow may be almost completely destroyed by chemicals (benzol, gold, etc.), i.e. aplastic anemia, or by proliferating malignant or leukemic cells, or may be extremely hyperplastic as in pernicious anemia, aleukemic myelogenous leukemia, spleen-liver (Banti's) disease, and yet the blood picture may be substantially the same The frequent cases of leukemia with a low leukocyte count ("aleukemic" leukemia) have been a source of continued interest Although many of these cases show very abnormal differential leukocyte pictures with the presence of primitive cells (lymphoblasts, myeloblasts or histiocytes), not infrequently proved cases of leukemia show no changes whatever in the differential picture and are usually accompanied with an erythrocyte picture resembling pernicious anemia Macrocytic anemia may be present not only in the "liver deficient" states (pernicious anemia) but in many other totally unrelated conditions certain cases of hepatic disease, myxedema, chronic nephritis, leukemia, lymphosarcoma invading the bone-marrow, and in chemical destruction of the marrow Usually leukopenia and thrombocytopenia are also present The bone-marrow biopsy is especially helpful in unravelling the diagnosis in these cases and may show either a "full" marrow or a relatively "empty" one In many cases it has been impossible to predict from the blood picture and the clinical findings whether the marrow will be hyperplastic or aplastic, so that in certain cases considered to be aplastic anemia, leukemia or lymphosarcoma will be found, and when pernicious anemia is suspected a hypoplastic marrow may be discovered In six cases the anemia, leukopenia, and thrombocytopenia were due to widespread involvement of the marrow by lymphosarcoma It is felt, therefore, that when a patient presents chronic anemia accompanied usually with a lowering of the leukocyte and platelet counts, and is refractory to liver and iron therapy, a bone-marrow biopsy may help to clear up the diagnosis

2 *Critique of the Puncture Method, Limitations of Both Methods* The phenomenal increase of interest in the study of the bone-marrow may be attributed to the rapidly growing interest in the so-called blood diseases and in the knowledge that fundamentally these represent disorders of the blood-forming apparatus, chiefly the marrow So intense has this interest become in the last few years that various short-cuts have been utilized in the attempt to obtain information as expeditiously as possible One of these short-cuts has been puncture of the sternal bone for the removal of material which has been called marrow

The bone-marrow biopsy was first performed by Ghedini¹⁰ in 1908, trephining of the tibia being done This method languished for many years only a few investigators, chiefly Zadek² and Peabody,³ being bold enough

to continue drilling into such a heavily protected marrow. Furthermore, the tibial marrow was normally acellular and gave information only in such hyperplastic conditions as pernicious anemia. Trephining of the sternal bone as a much simpler maneuver was introduced by Seyfarth¹ in 1923 and was then slowly taken up. Custer and his co-workers¹¹ set up certain standards in biopsy of the sternal marrow such as those relating to comparison of its cellularity with that found in other bones. Puncture of the marrow with a hollow needle as introduced by Arinkin⁶ and as modified by many workers has aroused great enthusiasm. This is indeed laudable since it indicates a greater interest in the marrow than was previously present but it also calls for some warning as regards interpretation.

As Custer¹¹ has pointed out, it is often dangerous to conclude from examination of a small piece of bone and marrow removed from the sternum the condition of the entire marrow which in size probably compares with that of the liver. In a scattered organ like the marrow, local conditions vary tremendously. This criticism must hold even greater weight for the material removed by puncture of the sternum with a hollow needle. This material looks very much like blood when aspirated, when smeared, it is found to consist mainly of mature red cells with a variable number of marrow cells, dependent both upon local conditions in the bone and marrow examined and on the technic. The first 0.5 to 1 c.c. contains many more marrow cells than the remainder of the aspirated material, so that several authors warn against removal of more than 1 c.c. Some investigators prefer to remove only sufficient material with which to make a few smears.

That the material removed by aspiration is mostly blood is confirmed by comparison of the "puncture" smears with the "trephine" smears made directly from bits of bone removed by curette from the trephine cavity. These show, as brought out above, that the ratio of nucleated red cells to whites is usually far greater in the trephine preparations, that the reticulocyte percentage is almost always much greater, and that the relative proportion of immature nucleated red cells is usually much greater in the trephine preparations. These observations suggest a number of interesting points some of which have already been emphasized, namely, that the nucleated red cells are intravascularly situated, the white cells growing extravascularly, that the more primitive nucleated red cells tend to remain adherent to the underlying endothelial surfaces, making them difficult to remove by simple aspiration. This is confirmed by the experiments of Maximow¹² who was unable to remove the most primitive erythroblasts from the marrow even by repeated perfusion. The same explanation probably accounts for the fact that the white cells greatly outnumbered the nucleated reds in the great majority of the puncture preparations. The comparative reticulocyte count may be used as an index of the degree of dilution of the immature cells with blood cells. The fact that the reticulocyte count (except in two instances of pernicious anemia under treatment) was always higher in the "trephine" than in the "puncture" preparations suggests that the puncture material is

obtained from a "part-way station" located between the bone-marrow on the one hand and the blood on the other. It would therefore seem improper to label the material removed by sternal puncture as bone-marrow since it appears to be chiefly blood in which are present a variable number of marrow cells. "Marrow juice" might be a better term.

Other criticisms of the technic of puncture have already been mentioned above. These are perhaps more important from a practical standpoint than those just discussed, namely, that the puncture material gives no idea of the topography of the marrow, that it is frequently deficient in cells when the marrow is cellular, that the deficiency in cells may be incorrectly interpreted when the marrow has become fibrotic as the result of previous invasion by tumor or leukemia, that it may fail to show Gaucher cells, leukemic islands, or small masses of proliferating metastatic cells, and that the interpretation of a hypoplastic or hyperplastic marrow is frequently impossible.

The criticisms of the puncture technic should not prevent us from conceding to it its relative simplicity and ease of technic as compared with the relatively formidable technic of trephination. Aside from ease of technic, it has certain obvious advantages: its applicability to infants and small children and its use for several examinations of the marrow in a case under continued treatment or observation. We feel, however, that once the idea of biopsy of the marrow has been entertained, it should be accomplished by as good a method as we have at our disposal rather than to rely upon the more or less haphazard results obtained from puncture despite its simplicity.

From the foregoing, the impression should not be obtained that the bone-marrow biopsy when performed by the trephine method which we have utilized must always give perfect results. As with all diagnostic methods, errors may be made. These are ordinarily due to poor preparations which are occasionally obtained, or to incorrect interpretations. The findings in the marrow may be stretched to make a preconceived diagnosis. Experience, and particularly the bitter ones of demonstrated error, have led us to postpone a definite diagnosis unless both the sections and smears have been examined and correlated, this inevitably means a delay of several days for the sections, but this amount of patience has been found valuable. In the absence of either the smears or the sections or of good preparations, it is advisable to hedge on the diagnosis, unless the condition is clear-cut. The smears are of no value when the marrow is extremely hypoplastic or fibrotic. The sections, however, may mislead us into making a diagnosis of leukemia as, for example, in the extreme hyperplasia of pernicious anemia with the presence of large numbers of primitive cells and many mitotic figures. Study of the bone-marrow when dealing with large sections from autopsies is difficult enough, with the small bits of marrow removed from the sternum at biopsy, it is advisable to keep one's diagnostic enthusiasm in close check. It is gratifying to note that with continued attention to these points our percentage of errors has been diminishing materially from year to year. With due attention to details, with proper preparation of both the smears and

sections, and above all with proper interpretation of what is seen, the biopsy should well repay the effort entailed in its execution. The data obtained from puncture material must always be surrounded with reservations since they are based on the findings in a fluid of uncertain origin and of mixed content. For research study, as Jaffe has pointed out,¹³ the puncture biopsy is certainly not to be relied upon.

3 Indications for Sternal Bone Marrow Biopsy The most obvious and important indication for sternal biopsy is in the diagnosis of obscure hematological problems, particularly in cases presenting persistent anemia, leukopenia, or thrombocytopenia, either singly or in combination. Because the biopsy is a surgical procedure, although a simple one, it stands to reason that all the various other diagnostic methods of probable value should first be carried out. The diagnosis of a case presenting obscure long-standing anemia may lead one into all sorts of by-ways far afield from what is technically hematology, but this simply illustrates that this field cannot be divorced from clinical medicine, of which it is an integral part. When complete physical examination, studies of the blood, roentgen-rays of the chest, the gastrointestinal tract, and the bones have not been productive of a diagnosis, the sternal biopsy may solve the problem. One should, however, be prepared for disappointment, for occasionally even this procedure fails to clear up an obscure case.

Knowledge of the condition of the marrow may at times be essential preliminary to the serious operation of splenectomy. Is a given case "Banti's disease," warranting splenectomy, or is it aleukemic myelogenous leukemia which is best left alone? In a recent case presenting severe rapidly progressive macrocytic anemia, splenomegaly, icterus, a normal fragility test, and lack of response to liver extract, it was important to know whether the marrow was merely hyperplastic or showed invasion by leukemic or malignant cells. When only extreme normoblastic hyperplasia was found, the operation of splenectomy was done and was followed by a spectacular recovery. Lawrence and Knutti¹⁴ have pointed out that it might be worth while to note the condition of the megakaryocytes in a case of thrombocytopenic purpura prior to splenectomy since if the marrow were found to contain large numbers of these cells, the operation would probably prove successful, if megakaryocytes were few, splenectomy might be of no value. Splenectomy is occasionally done for "aplastic" anemia, it seems wise to be sure of one's ground before this major operation is done. The caution should be made that in the presence of a very low platelet count the biopsy should be performed with unusual care and possibly postponed until after a transfusion of blood is given.

Another indication for sternal biopsy is in the differential diagnosis of splenomegaly. Seyfarth, who originated the method while stationed at an institute of tropical medicine, first used it in the diagnosis of chronic malaria and kala-azar. He felt that the procedure did not carry with it the dangers of splenic puncture, with possible rupture of the capsule and resultant hemor-

rhage This possibility has also deterred us from utilizing the latter diagnostic method, although such observers as Pittaluga¹⁵ have performed splenic puncture without accident in several hundred cases The diagnosis of Gaucher's disease which may present splenomegaly as the only abnormality has been alluded to above The spleen and the bone-marrow are so closely interrelated that study of the marrow may thus yield valuable information regarding the more inaccessible organ

A final indication for the sternal bone-marrow biopsy is in the research study of various hematological problems, the ultimate rationale being the gradual development of knowledge regarding their physiological pathology Studies of this type have already added to our understanding of the effects of liver therapy in pernicious anemia, and of aminopyrine in producing maturation arrest in agranulocytosis¹⁶ Many other problems remain to be worked out Again, the hope is expressed that hit-or-miss methods should not be tolerated

SUMMARY AND CONCLUSIONS

The diagnostic value, indications, and limitations of the sternal bone-marrow biopsy were discussed In 20 consecutive cases, the trephine and the recently popularized puncture methods for biopsy of the sternal marrow were compared With use of the trephine, two types of preparations are obtained sections made from the removed plug of bone, and smears made from bits of bone removed from the edges of the trephine opening With the puncture, a sanguinous appearing material is aspirated, from which only smears can be made

A comparison of the smears made with the "trephine" and the "puncture" methods showed a far greater cellularity in the biopsy preparations, a greater reticulocyte percentage, a greater number of erythroblastic cells relative to granulocytes, and a greater number of early nucleated red cells The puncture preparations frequently consisted almost entirely of red blood cells interspersed among which were some marrow cells The sections obtained at biopsy not only gave one an idea of the general topography of the marrow, but of its general degree of cellularity, the presence or absence of islands of leukemic or neoplastic cells, and in certain cases of connective tissue replacement Combined study of the sections and of the smears has proved to be of much greater value than study of the one type of preparation alone

Puncture biopsy of the sternum is to be criticized because the material obtained is usually not marrow but a variable mixture of blood with marrow cells ("marrow juice"), because lack of cellularity in this aspirated material does not necessarily mean lack of cellularity in the marrow itself, because primitive erythroblastic cells, present in the marrow, are frequently not obtained, and because abnormal islands of neoplastic and leukemic cells are either not obtained or if seen may be misinterpreted because of the lack

of topographical relationship The chief advantage of puncture biopsy is its simplicity, but this is greatly outweighed by its inaccuracy When the procedure of bone-marrow biopsy is contemplated, we feel it should be done in as careful a manner as possible since, even with the best technic, interpretation may be difficult

NEUROLOGIC MANIFESTATIONS IN "HYPOGLYCEMIC SHOCK" (SAKEL)

By LEWIS A. GOLDEN, M.D., *New Orleans, Louisiana*

PRESENT attempts to treat schizophrenia and other psychoses with hypoglycemia induced by large doses of insulin, afford the opportunity of observing at one's leisure, many interesting neurological manifestations seldom otherwise witnessed

Through the courtesy of Dr. John R. Ross, Superintendent of the Harlem Valley State Hospital, N. Y., and the kindness of Drs. I. Murray Rossman, William B. Cline, Jr. and O. Schwoerer of the male service and Dr. A. Goulacher and Dr. Pellens of the female service I was among those privileged to observe this phase of their work on the "Insulin Wards." The method used was that of Sakel who had personally trained the staff during his stay at the Harlem Valley State Hospital. Their scientific and conservative attitude left a lasting impression of the reliability of their evaluation of the treatment, which we hope will soon be published. We witnessed most encouraging results in a group of patients characterized by Dr. Sakel himself as "deadwood" and offering little expectation of improvement. I am sure that these interesting results will be reported in detail by those in charge of the work at a later date.

Many of the manifestations which accompanied the hypoglycemic state were of particular interest to the neurologist. These neurological pictures were so varied and striking in their combination and appearance that in all probability they are now being seen for the first time in this condition of severe hypoglycemia. In my experience, none of these have been described in accidental hypoglycemia arising as a complication of diabetic treatment or as a symptom of pancreatic adenoma.

I found it useful for my own comprehension of these complicated neurologic events to arbitrarily divide them into three categories, namely:

(1) "Prolonged" manifestations which were those occurring for a longer period during the four to five hours of treatment,

(2) "Sudden" manifestations which were those which occurred suddenly and usually toward the end of the treatment.

(1) The "prolonged" manifestations

Soon after the insulin had been given, the patient ordinarily remained quiet and resting. During the second hour, when diaphoresis usually was well established, there would ensue either somnolence, restlessness, mild

* Received for publication August 9, 1937

From the Department of Medicine, Division of Psychiatry, Tulane University Medical School, New Orleans, Louisiana

excitement, or shouting. This usually passed off as the hypoglycemic state progressed into deeper coma. In this phase one could observe

(a) Quick, jerking movements of the arms, legs, body, and restless tossing of the head. A sudden flexion, but less frequently extension of both arms was extremely common. These movements often recurred for an hour or more during the treatment and as often as 15 to 20 times per minute, although the rate varied greatly. Touching or shaking the patient frequently initiated such "flexor arm jerks."

(b) Some patients exhibited prolonged sucking movements of the lips. No special emotion could be noted in the facial expression during these movements. At times, there was marked grimacing of the face accompanied by bilateral athetoid movements of the extremities.

(c) There were episodes initiated by flushing of the face, dilation of the pupils and labored breathing. These were associated with rigid extension of the lower extremities, bilateral adduction and extreme internal rotation of rigidly held arms. The wrists were rotated to hold the palms outward. The fingers were most often tightly clenched into the palm with the thumb projecting characteristically between the index and middle finger, or the ring and middle finger. The eyelids were often retracted widely, producing a picture of extreme fright. The whole movement was slow and rhythmic. After about thirty seconds to one minute the arms and legs would relax and resume a neutral position until the next movement began again. This picture at its climax, clinically suggested the attitude of decerebrate rigidity.

(d) There occurred at times only a partial manifestation of the above. The arms would rotate, the palms face outward, but the limbs would remain fairly well relaxed and this position would be maintained for long periods without any interruption.

(e) Irregular, thrashing, apparently purposeless movements of the arms and legs were frequently noted. At times there seemed to be definite attempts to brush away the physician's arm or the towel on the patient's forehead. These movements suggested true defense reflexes. The patient would often strike the bed, the wall, or his own face during this activity.

(f) The deep reflexes were difficult to evaluate because of the constant spasms in the extremities which interfered with their elicitation. However, following the somnolent stage, the Babinski reflex would appear and then become sluggish as the patient approached deeper coma. The corneal reflex also disappeared in the later stages of coma. More often the Babinski appeared as part of a general flexor withdrawal reflex but toward the deeper stages of coma it could be elicited alone before its final disappearance in deepest hypoglycemia. Its appearance or disappearance apparently mirrored the depth of the hypoglycemic shock.

(g) Slow "trombone like" movements and irregular jerks of the tongue often were seen. A spontaneous clonus of the lower jaw, and clonic movements of the upper eyelids sometimes appeared for a short while.

(h) The extremities sometimes assumed a posture resembling that seen during the movements of dystonia musculorum or athetosis, however, they remained fixed in these positions, suggesting the term "frozen athetoid movements" for their description. Dr Dussik told me of seeing true hemiballistic movements as well as athetoid position of the hands in his Vienna material.

(i) Transitory hemiplegias sometimes occurred. Drs. Cline and Schwoerer told me of seeing a hemiplegia which lasted for nine hours. I observed several transitory hemiplegic states. In one instance, a case on Dr. Goulacher and Dr. Pellens' service showed a transitory palsy of the left side of the face which preceded an epileptic convulsion.

All the movements and postures just described were most often bilateral but at times unilateral.

(2) "Sudden" neurologic manifestations

(a) Convulsive seizures frequently occurred and could be clearly recognized from the other convulsive movements of a more prolonged character in most instances. It was often difficult for me to decide exactly when a series of convulsive movements could be grouped as a seizure. The definition of what constitutes a true epileptic seizure is still highly unsatisfactory. Certainly if we call mild disturbances of consciousness with slight twitching a petit mal attack in everyday medicine, it then becomes quite difficult to state that a series of severe convulsive movements in an unconscious patient is not a true epileptic seizure. Sakel himself uses the term in a rather indefinite way, and so do many others.

(b) There occurred in about a dozen instances according to the doctors a sudden dramatic complication usually toward the end of the treatment, one of which I witnessed. Three cases were of great severity while the others were said to have been milder. These alarming manifestations of such a severe complication were particularly frightening to the onlooker when seen for the first time. Drs. Rossman, Cline and Schwoerer felt that their observation may represent a specific type of complication with special prognostic features. Dr. Dussik stated that in his experience it had occurred only five times in about 5000 treatments. It usually appeared as follows. When the regular proceedings for the termination of the hypoglycemic state had been instituted, the patient would fail to react. By previous experience the doctors had found that if such a patient did not react in 45 minutes even when intravenous glucose had been given, trouble was in all probability to be expected. The patient at the time was often noted to have very small pupils, which then slowly dilated and were associated with marked flushing of the face. There then ensued an excited phase with convulsive movements, contortions, rigid attitudes and extremely labored breathing lasting for 15 to 20 minutes. This phase was so severe that the patient appeared to be in extremis and completely exhausted. The movements would then slowly subside in severity and duration, the pupils return to more normal size, and the patient relax in apparent exhaustion.

with shallow slow respiration. After a lapse of 10 to 20 minutes another active phase would begin, augment to a frenzy of labored irregular movements and again subside. These alternating periods of activity and relaxation at times continued for one to two hours, diminishing in duration and severity with each attack.

It seemed as if the whole central nervous system was thrown into a frenzy of disorganized activity. There were recognizable hemiplegic attitudes, extrapyramidal manifestations of transitory cog-wheel rigidity, and signs of midbrain involvement in disturbed extraocular movements—the eyeballs moving asynchronously. There were also signs suggestive of disordered thalamic and medullary control of temperature, pulse and respiration, which appeared entirely disassociated from their usual relationship. For example, the temperature being 104.2° F, the pulse would be 160 and the respirations as high as 80 per minute. There were in addition manifestations of overactivity at the lowest levels of the brain stem as judged by the occurrence of opisthotonus and the attitudes of decerebrate rigidity. There was also evidence of overactivity in the autonomic nervous system, the dilation of the pupils, flushing of the face and rapid pulse as sympathetic overactivity, the contraction of the pupils and pallor as parasympathetic overactivity. It was extremely difficult to separate these rapidly changing pictures and fit them into neurological schemes. The general impression was that of an overactive, totally disorganized central nervous system being thrown into activity in a rhythmical manner. It suggested to me the term “neuro-physiologic crisis.” All of the neurologic manifestations, in spite of their severity, were reversible in character and the patient awoke from his hypoglycemic coma with no trace of the “neurologic storm” through which he had passed. He then would ultimately quiet down and remain stuporous. After full awakening he would still show some evidence of mental confusion for many days and at times as long as two or three weeks. The doctors had made the interesting observation that patients who experienced this severe complication usually emerged from this confused afterstate with definite signs of progressive improvement.

It is at present difficult to understand what occurs during this hypoglycemic treatment and what sort of nervous involvement produces these neurological pictures. Speculation, in the present state of our knowledge, may be interesting but is quite valueless. A great deal of work must be done. We hope that future study and evaluation of the hypoglycemic therapy may disclose some information which might help us to explain these unusual neurologic states. Until then, we must be content with close observation and careful recording of data.

MOTOR INVOLVEMENT OF THE CENTRAL NERVOUS SYSTEM IN PELLAGRA, A REPORT OF 2 CASES¹

By M A BLANKENHORN, M D , *Cincinnati, Ohio*

NERVOUS and mental symptoms are conspicuous in textbook descriptions of pellagra, but only the more extensive studies describe motor disturbances other than peripheral neuritis. Hemiplegias and paraplegias are described as being rare and generally occurring in the severe and terminal stages. Grinker¹ in a recent textbook states briefly that a picture similar to the neurological complications of pernicious anemia may appear but are never as severe or progressive. He states further that the lesions of the nervous system in pellagra are "not irreversible."

With newer methods of treatment, especially with new forms of diet and vitamin concentrates, the severe and so-called incurable phases of pellagra can be cured² and profound disturbances of the central nervous system reversed. The cases here presented, one resembling hemiplegia and the other diplegia, were totally disabled and even "helpless," one for three weeks and the other for six weeks. With intensive dietary treatment both became well. In each case chronic alcoholism was the obvious predisposing cause of pellagra, but it is now generally believed that "alcoholic pellagra" and endemic pellagra are the same disease. In 1928 Klauder and Winkelman³ reported finding "central neuritis" in every case of pellagra which they examined histologically, a total of 11 cases, and in many cases of alcoholism in which a diagnosis of pellagra had not been made.

The remarkable recovery of the patients here described, when treated as pellagrins, suggests that the motor involvement was really part of the pellagra syndrome.

CASE REPORTS

Case 1 L C, a 48 year old Negro laborer, was admitted to the Medical Service of the Cincinnati General Hospital April 18, 1936, complaining of "fits" of two days' duration. He gave a history of two similar attacks 10 years previously, and of alcoholism, up to one pint daily, for years. During the three months prior to admission he noticed loss of appetite, soreness in the chest and abdomen, slight loss of weight and aching and weakness in the lower extremities. The day before admission he had two generalized convulsions which he could not adequately describe, even though he claimed he was conscious throughout the "fit."

Physical examination revealed a fairly well developed, fairly well nourished Negro

¹ Read in part at the Ninth Annual Meeting of the Central Society for Clinical Research, Chicago, Illinois, November 6, 1936

who was restless, disoriented, confused, at times delirious, and who made purposeless choreiform movements of his arms and legs. His lower extremities were weak and he was unable to walk. The right pupil was irregular and larger than the left, both reacted only slightly to light. The skin and mucous membranes showed the diagnostic signs of pellagra. The margins of the tongue were smooth and red, and areas of leukoplakia were present beneath the lateral margins. The gums and oral mucous membranes were also red and beefy. The skin showed increased pigmentation, roughening and desquamation of the dorsum of the hands, and of the feet, elbows, and knees. The lesions of the hands were sharply demarcated from the healthy skin of the forearm. Examination of the central nervous system showed knee jerks which were thought to be normal. Ankle, abdominal, and cremasteric reflexes were absent. There was no ankle clonus or Babinski reflex. Sensory examination was impossible. Blood pressure 130 mm of Hg systolic and 80 diastolic.

Laboratory Findings Hemoglobin 80 per cent (Sahli), red blood cells 3.9 millions, white blood cells 14,000 with 82 per cent neutrophils. Urine Specific gravity 1.032 (later becoming normal), sugar and albumin 1 plus, many granular casts. Later examinations were negative. Blood Kahn test negative. Spinal fluid examination negative, except for positive protein on admission, later examinations were normal. Gastric analysis following Ewald meal 24 per cent free HCl, 54 per cent total HCl. Blood sugar, blood urea-nitrogen, and carbon dioxide combining power were normal.

Progress During the first two days of hospitalization the patient had 18 or 20 "convulsions," each consisting of clonic twitching of the extremities, usually of the lower extremities only, accompanied by opisthotonos, incontinence, and striking mental excitement. He was not unconscious during these attacks. For several days after admission he was delirious and uncooperative. Incontinence of urine and feces persisted for six weeks after admission. He did not have diarrhea at any time during the course of his disease. Treatment with a high caloric, high vitamin diet, intramuscular liver extract and brewers' yeast induced definite and rapid improvement in the dermal lesions, tongue, and mental state of the patient. He continued, however, to show marked motor incoordination with a rigidity so great that he was unable to leave his bed or to feed himself. At times his picture suggested a left spastic hemiplegia. On May 11 (twenty-fourth hospital day), he was examined by Dr. H. D. Fabing of the Division of Neurology who found spasticity of the left arm with hyperactive reflexes, absent reflexes in both legs, fascicular twitching in all muscles, Oppenheim on right and Gordon on left. He made a diagnosis of "toxic encephalopathy with left sided focal signs." Dr. Fabing again saw the patient on June 3 (forty-fifth hospital day) and described slight left facial weakness, increased deep reflexes on the left, bilaterally absent ankle jerks, bilateral Gordon, Oppenheim on the right, groping movements of the hands, and speech containing jargon. His interpretation was "Diffuse encephalopathy (demyelinating) with 'pellagra,' with a suggestion that there might be accompanying peripheral neuritis."

Rapid improvement continued and 11 weeks after admission, the patient was discharged. At that time he was mentally clear, and was able to walk about the ward rapidly and without help. However, he still complained of inability to use his legs as well as formerly and there was slight residual rigidity of the left arm. Eight months after discharge an investigator learned that he had gone South to his old home to look for work, supposedly well.

Case 2 T. C., a 28 year old negress, was admitted to the Psychiatric Service of the Cincinnati General Hospital May 12, 1936 in a state of mild delirium.

Present Illness During the four years preceding admission, this patient had been consuming large amounts of strong alcoholic beverages. Her sister described two previous spells of extreme nervousness accompanied by visual hallucinations.

During the three months prior to admission, she had become progressively weaker and, because she was "unable to prepare her meals," had been eating a diet which her sister felt was deficient. Two days before admission she suddenly screamed and began to make purposeless movements and meaningless sounds. Soon afterwards she had visual hallucinations. This condition persisted until admission.

Physical examination showed a well developed but poorly nourished black female who was oriented only intermittently as to time and place. She refused to answer questions and made slow purposeless movements of her entire body, head and extremities, and picked at her clothing, breasts, vulva, and anus. At times she sat up in a bizarre manner. The skin showed diagnostic signs of pellagra,—namely, rough, desquamating dermal lesions were present over the hands, wrists, feet and ankles. The tongue and mucous membranes were normal. Reflexes were equal and active, no plantar reversal. Temperature 99.2° F, pulse 96, respirations 20. Blood pressure 135 mm of Hg systolic and 90 diastolic.

Laboratory Findings Red blood cells 4.63 millions, hemoglobin 80 per cent, white blood cells 12,000. The urine was normal, the blood Kahn test strongly positive, and the spinal fluid negative. Gastric analysis showed no free hydrochloric acid before or after histamine.

Progress For several days after admission the patient continued to be mentally disorganized, restless, and to have hallucinations and periods of intense fear and severe insomnia. These symptoms fluctuated considerably from day to day. She became unable to walk and was incontinent of urine and feces. Neurological examination revealed peripheral tenderness, great incoordination, and striking bilaterally symmetrical rigidity, especially of the legs. Through the courtesy of Dr. E. A. North of the Division of Psychiatry she was seen on her seventh day of hospitalization by the author who concurred in the diagnosis of pellagra. Treatment, which had been started on admission, consisted of a high caloric, high vitamin diet, dry powdered brewers' yeast, parenteral liver extract and moderate sedation. She improved rapidly and within three weeks she was able to feed herself and could walk moderately well, although spasticity of her legs persisted and she was still mentally confused. Despite the fact that she was known to be chronically addicted to alcohol, she was not classed by the psychiatrists as definitely of Korsakoff's syndrome and no opinion other than the diagnosis of pellagra and chronic alcoholism was offered as to the cause of the striking motor disturbances. On her twenty-seventh day of hospitalization (6-8-36) she was transferred to Longview Hospital for the Insane. Upon discharge from that institution 10 weeks later, she had no abnormal motor behavior, could walk rapidly with perfect coordination and was mentally clear. When seen one year later, this patient stated she was no longer drinking, she appeared to be in excellent health, and had had no return of symptoms since leaving the hospital.

COMMENT

Two adults who had motor involvement of the central nervous system at a time when they had diagnostic pellagrous lesions are presented in the present report. Both patients were addicted to alcohol. They had severe motor disturbances characterized by rigidity, inability to walk, and slow choreiform movements. The paralysis in one case was hemiplegic in type, while in the other it was paraplegic. Following the administration of a high caloric, high protein diet and large amounts of powdered brewers' yeast, the pellagrous dermatitis disappeared and the motor function of the central

nervous system was restored in both cases. The observations in this report show that motor involvement of the central nervous system, like glossitis and dermatitis, is part of the syndrome of pellagra and responds as do these symptoms to antipellagic therapy.

NUTRITIONAL DISTURBANCES OF THE EXTREME SOUTH*

By J H MUSSER, M D , F A C P , *New Orleans, Louisiana*

KNOWING the life long interest that Dr Pratt has had in dietetics, the keen enthusiasm he has shown on the subject of nutrition, and appreciating the magnificent dietetic facilities that he has organized in his clinic, it seems appropriate to present some observations on the nutritional disturbances that are observed in the far South

There is considerable variation in the type of patients seen in the wards of a large general hospital in the South as contrasted with the wards of a Northern metropolis. In the North it is customary to see many cases of rheumatic heart disease, for example, but in the South these cases are relatively rare. True lobar pneumonia is an exception in the South and never are cases observed in large numbers at one time as they are in the late winter in northern climates. On the other hand, there are seen in the South patients who have sprue, who have pellagra, who have malaria, amebic dysentery, bacillary dysentery and other types of disease which are relatively infrequent in the North. Many of these disorders are representative of the so-called tropical diseases but actually diseases observed in the tropics, or the sub-tropics as is New Orleans climatically, are pretty much the same diseases that are seen in temperate climates. The difference is merely quantitative rather than qualitative. More cases are seen probably of sprue or pellagra in the South and fewer cases of pneumonia than in the North, but as many cases of hypertensive heart disease or of syphilis are seen in the tropics as are seen in the North. As brought out recently by Haines, sprue is very much more common in the North than it was thought to be at one time. Alcoholic pellagra is observed repeatedly in the North. At one time the population of Philadelphia was almost decimated by malaria. Amebic dysentery is ubiquitous. Leprosy is world wide in its spread. Really it might be said that, with the exception of certain dermatologic conditions, diseases of exclusively tropical distribution are almost non-existent.

Just as the so-called tropical diseases are more frequent in the South than in the North, likewise there is another group of cases which seem to be commoner in this southern section of the country than elsewhere. Perhaps this impression is erroneous and the apparent greater frequency of these disorders depends upon our searching for them more carefully and being more on the watch for them than in the past. These disorders are

* Received for publication August 3, 1932

dependent upon some nutritional inadequacy. They exist as clear-cut, definite entities which depend upon such extrinsic causes as faulty diet or they may, on the other hand, be dependent upon some inherent defect in the organism as in pernicious anemia. The clear-cut syndromes may develop as result of vitamin insufficiency, inadequate and improper mineral intake or a lack of protein. It is my purpose to illustrate succinctly the expressions of some of the clear-cut definite entities and how they can be handled and then to discuss rather briefly the indefinite ill health which may be associated with nutritional faults which do not produce actual nosologic entities.

PELLAGRA

In Louisiana the incidence of pellagra waxes and wanes but on the whole it seems to be less common than it was a few years ago. It is surprising how severely ill some of the patients are who come into the Charity Hospital suffering from pellagra. It is also astonishing how these people sometimes fail to respond to what is now considered to be more or less a standardized treatment. Illustrating this is the case of Mrs. A. who was brought into the hospital June 1937 with a severe diarrhea. She had been confined to bed for some weeks, she showed very little dermatologic reaction, her mentality was distinctly obtunded. This woman was markedly undernourished, dehydrated, with extremely sore mouth and with a proctitis and extremely severe vaginitis. She was given fluids by vein, a high caloric-protein diet largely liquid on account of the stomatitis, powdered brewers' yeast, vitamin concentrates and even liver extract hypodermatically. In a few days improvement of the mouth and of the mental state was quite decided. The proctitis and vaginitis showed no signs of improvement. The diarrhea was controlled. In spite of temporary improvement the patient relapsed and died a few days later. This patient had in her diet an over abundance of the important elements, the lack of which may play a part in the production of pellagra. In spite of this, death occurred rather promptly. It is most discouraging in patients of this type to carry out the indicated lines of therapy and to get no result, but these cases are quite common. Incidentally it might be noted that the so-called alcoholic pellagra is rather uncommon in our wards.

PERNICIOUS ANEMIA

The most remarkable feature of pernicious anemia that I have observed in a woman's ward is the extreme degree of anemia these people have when they come into the hospital. It is perfectly astounding. A large number of these patients are seen. Illustrating the statement as to the severity of the anemia, is the case of Mrs. B. who entered the hospital on account of weakness, loss of weight and loss of appetite. This woman had been sick about six months. On admission to the ward she had a red cell count of about 1,000,000, hemoglobin 3.67 grams, mean corpuscular volume of 134

cu mm but no absence of free HCl Parenteral administration of liver extract brought about a sharp reticulocyte response and improvement took place very rapidly When discharged from the hospital in about a month the blood count had reached practically normal figures, mean corpuscular volume approached normal and in every way the patient was to all intents and purposes entirely well

Unfortunately on account of lack of financial resources and because many of these patients live in country districts where the free clinic is not available, they leave the hospital in excellent shape and return again in a period of about six months to a year or two almost as anemic as they were when they first entered We can build them up again, out they go and then sooner or later they return I had one patient who has been in the hospital seven different times, admitted each time with a high degree of anemia and each time she goes out in excellent condition

Unlike pellagra, pernicious anemia is a most satisfactory disease to treat Since the introduction of liver extract I have not observed a single death of a patient from this disease

SPRUE

In a hospital ward of 21 beds which are always filled, probably four or five cases of sprue can be expected during the year One of the cases that I have observed was that of Mrs S who went into the hospital with severe diarrhea, stomatitis and an extreme degree of emaciation, weighing 59 pounds I am recounting this case because I have kept in constant touch with her for nearly eight years and she is apparently well Mrs S was placed upon a diet consisting largely of bananas and raw pancreas After many days of encouragement to get her to follow this regime she was finally able to eat about two or three dozen bananas a day, her improvement began at this time After a period of six months she had more than doubled her weight The diarrhea disappeared and the anemia had gone She now retains a weight of 130 to 135 pounds and has continued to eat bananas to the extent of three or four a day From time to time she has slight diarrhea and as soon as this develops she takes a dozen or two dozen bananas and restricts her diet almost entirely to this article of food In a day or two the diarrhea will have gone and she is back again to normal health This patient never had liver extract Nowadays we are including with the banana diet injections of liver

Sprue was at one time thought to be solely a tropical disease but Haines calls attention to the relative frequency of sprue in North Carolina, and Snell records nine cases appearing at the Mayo Clinic in one year Undoubtedly sprue has been often misdiagnosed as pernicious anemia It is important to make the correct diagnosis because, as Haines writes, these patients with sprue can be cured if the proper diagnosis is made and if proper treatment is instituted they will not have to go through life living on liver

SCURVY

Once in a while I see obvious cases of scurvy but they are relatively rare. On the other hand, subclinical scurvy is by no means uncommon. A young pregnant woman was admitted to my ward with petechiae and a story of having had hemorrhages, small in amount, from the mouth and from the rectum. The blood studies were entirely negative. Although she had been taking vitamin C to a limited extent she, as every pregnant woman, required a superabundance of vitamin C which she had not been getting. The purpura cleared up and there was no further hemorrhage after giving her large quantities of orange and tomato juice.

BERIBERI

In a group of Louisianans who are poverty stricken the diet consists largely of red beans and rice. These people often develop beriberi. Such patients are seen from time to time so that we are always on the watch for it and are not surprised when these cases appear. A young person came into the hospital with an atrocious mouth, Vincent's angina. Several weeks prior to the development of the mouth condition there was marked weakness of the legs and some anemia. The condition became very much exaggerated when the patient was unable to eat on account of his sore mouth. Upon historical and physical examination the typical symptoms and signs of mixed beriberi were found to be present. After curing the mouth condition, the institution of a diet which contained vitamin B to excess promptly relieved the symptoms. From time to time I have seen patients who have recurrent attacks of beriberi. It may be noted that improvement is prompt and satisfactory after the first or second attack. The subsequent attacks fail to respond to treatment and the patient may be left permanently crippled.

PROTEIN DEFICIENCY

Quite commonly there is observed among our clientele patients who have voluntarily, or through poverty, restricted their protein intake to a point where anemia develops and even edema ensues. These people do not have edema as a result of depletion of plasma proteins through a nephritis or a nephrosis, but merely as a result of insufficient intake. Probably the most outstanding case was that of a young woman who had been advised by her physician, on account of a gall-bladder disorder, to withhold proteins. Conscientious and faithful in observance of the doctor's orders, this woman for a period of six months stopped eating every type of protein. When she was first seen she had marked edema of the legs, so marked as a matter of fact that she had some difficulty in getting about. There was complete reversal of the serum albumin-globulin ratio and serum albumin was well below edema levels. She was given a dozen eggs in the course of the next 12 hours and the diuretic effect was astounding. Edema quickly disap-

peared and since then she has had no further trouble. As in every general hospital a certain proportion of the people are admitted on account of extreme inanition. It is not uncommon to find these people with varying degrees of edema which disappears when they are given a well rounded diet.

CHRONIC DIETARY DEFICIENCY

Excluded from this group are those patients whose diet contains ample energy requirements, likewise those people who have some distinct and definite disease which may account for an excessive expenditure of energy, such as exophthalmic goiter, or who lose ingested food through the alimentary tract as the result of diarrhea. The patients of the group, to which I am referring, are not, strictly speaking, undernourished, but their body weight is subnormal and they have a variety of symptoms which may be attributed to an illy balanced diet. To those symptoms Sodeman and I have applied the term chronic dietary deficiency. These patients do not present clinical entities which have a nosologic significance. Possibly many of the cases might be called subclinical forms of diseases such as beriberi or scurvy or what not. Rather than mentioning specific instances which are extremely common in our section of the country, it may be more appropriate to run over briefly some of the expressions of this type of disorder. These people are usually thin, and anemia is a constant concomitant. We have seen patients who have macrocytic anemias yet do not have pernicious anemia, but more common is microcytic anemia. Some of the signs and symptoms that they present may be due to vitamin A deficiency, such as photophobia and dry skin. Gastrointestinal symptoms are common with dyspepsia, anorexia, constipation. There may be nervousness, headache and irritability. In younger individuals growth is impaired, dental caries may be observed and gingivitis with bleeding is common. They often have susceptibility to infection and vague aches and pains. They have ease of fatigue and weakness. Paresthesia and tingling of the extremities are by no means uncommon. These patients may have the features of the neurotic and the complaints of the neurotic. An analysis of the diet of these patients with chronic dietary deficiency, and a complete dietary history will show that they restrict the protein, fruits and fresh vegetables in their diet, through poverty or idiosyncrasy. Butter fat may disagree with them and they often eliminate that from the diet. Frequently their main article of food is carbohydrate. They live on what I have termed a "white diet." If these individuals, usually for economic reasons unable to pay for a well rounded diet, can be given a liberal supply of fish, meat, eggs and cheese, irradiated evaporated milk, fruits, tomato juice and cod liver oil, their improvement is sometimes astounding and the disappearance of the so-called neurotic symptoms is almost miraculous. Strange to say, chronic dietary deficiency is rarely observed in the negro, although they are the poorest section of our population. However, to the negro food is the first thought in his mind.

when it comes to spending his wages, whereas other considerations such as where and how he lives, how he clothes himself and so on are entirely secondary

CONCLUSIONS

No attempt has been made to detail systematically the nutritional disorders that are observed in the South. The more common ones have been discussed in a general and rather informal way. These disorders are extremely common and are most satisfactory to treat, with this proviso, and it is a big one, that funds be available to supply the patient with the proper foods

.

COFFEE AS A CAUSE OF CARDIAC PAIN

By ROBERT L. LEVY, M D , F A C P , *New York, N Y*

THERE are many disturbances, both anatomical and physiological, which may cause pain in the region of the heart. To differentiate them and, in a given case, to determine the particular condition giving rise to discomfort, is the first requisite in diagnosis. The accurate definition of etiology often makes possible the distinction between a mild and a grave malady, it is essential for the institution of effective therapy.

As a cause of cardiac pain the drinking of coffee has received but scant attention, though briefly mentioned by some of the older clinicians. For example, Kiehl¹ states that "poisoning by coffee may cause more complete systole of the ventricles, palpitation, oppression and anginoid states." He ascribes these effects to two causes: first, to direct stimulation of the heart, and second, to more forceful contractions which represent a compensatory reaction to peripheral vasoconstriction. Allbutt² remarks that "coffee drinkers, and some nervous persons are liable, especially in later life, to attacks of cardiac irregularity, especially during and after meals, with epigastric distention, oppression, or even pain, a series which, with some degree of arteriosclerosis in radial artery and aorta, may simulate *epigastric angina* very closely." In the latest edition of his manual of pharmacology, Sollmann,³ in discussing the toxicology of caffeine, says "With larger doses, the pulse is full and hard, quickened or slowed, with palpitation and precordial distress (sometimes anginal attacks)." In a recent monograph I have made brief reference to the cardiac pain due to coffee⁴, but most of the newer texts on diseases of the heart fail to mention it, although a number of other toxic effects are noted, particularly premature contractions. In the following two cases, the relationship between the drinking of coffee and the occurrence of pain seemed clearly established.

CASE REPORTS

Case 1 A physician, aged 38 years, was first seen in December 1927. He complained of precordial pain of two months' duration. He had enjoyed excellent general health. He played squash two or three times a week without discomfort. He was working hard and nervously awaiting the birth of a second child. Up to three weeks before his visit, he smoked six or eight pipefuls each day. He rarely took alcohol. He drank two large cups of coffee and two cups of tea daily.

The present illness began two months previously, with an arrhythmia due to premature beats. He stopped smoking on this account. For four weeks he had

* Received for publication July 28, 1937.

From the Department of Medicine, College of Physicians and Surgeons, Columbia University, and the Medical Clinic of the Presbyterian Hospital.

noted pain in the chest, usually precordial, but sometimes substernal. This was not severe, was unrelated to effort and lasted for several hours or even for several days. There was sometimes a sense of heaviness in the left arm. He played squash without aggravating the discomfort. There was no dyspnea. He was much upset because of the possibility that his symptoms indicated the presence of coronary sclerosis.

On examination there were no signs of organic cardiac disease. The heart rate was 60, the rhythm regular. The sounds were normal. The blood pressure was 118 mm Hg systolic, 72 diastolic. The heart was transverse in position, but was not enlarged on roentgen-ray examination. The electrocardiogram showed a moderate degree of left axis deviation, with inversion of the T-wave in Lead III.

He was reassured and advised to stop taking coffee and tea. He was told to resume smoking in moderation and to continue with his usual exercise.

One month later he reported that the pain in the chest had completely disappeared and that a cup of coffee or tea would bring it on as before. Even Sanka induced discomfort. Because he was still somewhat skeptical as to the relationship of coffee to his pain, the following experiment was carried out. At intervals of a week, for four consecutive weeks, he was sent a capsule, the contents of which were not known to him. Two of the capsules contained 0.13 gm (2 grs) of citrated caffeine, the others an equivalent amount of milk sugar. He was able to distinguish between them in each instance, the caffeine precisely reproduced the pain which he had been having, the milk sugar caused no symptoms.

He was seen again seven months after his first visit. He had attempted to take coffee, but found that it again caused pain. Examination was negative, as before.

In November 1932, the patient reported that his sensitiveness to coffee had disappeared and that he could now drink it without subsequent pain.

In March 1937, he reported that he had been drinking coffee during the intervening years without recurrence of cardiac pain. At times, however, about an hour after taking a cup of coffee there was marked sweating of the palms of the hands. He was convinced that coffee caused his original symptoms.

Case 2 A lawyer, aged 40 years, was first seen in December 1930, complaining of precordial pain which had been present, at intervals, for a year. At 18, he had nephritis and was out of school for a year. Subsequent tests of renal function showed a good recovery. He was refused for military service in 1918, because of albuminuria. There had never been hypertension or edema. He took two cups of coffee each day, but no tea. He did not smoke or use alcohol. He was of a worrisome nature and dreaded trial work, which, because of the limited business available, he was obliged to undertake. He had been married 12 years, his wife and two children were living and healthy.

The present illness began the year previously. He was in the habit of playing squash several times a week. Always, after exercise, he noted upper precordial pain, not severe and without radiation. This would usually last for several hours, "it felt as though a muscle had been pulled." There was a tender spot in the region of the third left interspace. The pain never occurred during exercise, but always after it. He could walk briskly for two or three miles, but on sitting down later would have an aching sensation in the precordium for two or three hours. There was no dyspnea. He consulted a physician, who suggested that an electrocardiogram be taken by a diagnostic laboratory. The report stated that the myocardium was severely damaged. He was advised to give up all exercise and to curtail his work. He was naturally greatly distressed.

The patient was a high-strung, introspective man. Physical examination was negative. There was no evidence of arterial or arteriolar sclerosis. The heart rate was 80, the rhythm regular. The sounds were of good quality. The blood pressure was 146 mm Hg systolic, 86 diastolic. There was no enlargement of the heart by orthodiagraphic measurement. The electrocardiogram showed slight notching of the

S-wave in Leads I and II, and of R in Lead III. There was also very slight elevation of the S-T segment in Leads II and III (figure 1). The urine contained a faint trace of albumin, but no casts or blood cells.

The patient was told to resume a normal life, including the playing of squash. He was advised to give up coffee.

FIG 1 Electrocardiogram of Case 2. For description, see case report in text.

Two months later, he stated that he had an occasional twinge of pain after violent exercise, but this was negligible. He was still working under strain. The blood pressure was 136 mm Hg systolic, 84 diastolic. In April 1934 (four and one-half years after his first visit) he stated that he had never been so well. The cardiac pain had completely disappeared. He was playing squash and working hard.

He was seen again in June 1935. He was much happier and had been very successful as a lawyer. He had given up squash, but played doubles at tennis and walked briskly without discomfort. He again wanted an appraisal of his condition. Examination was essentially as previously described. The electrocardiogram was exactly as it had been on the first examination.

The patient reported by telephone on July 9, 1937. His general health was excellent. There was no recurrence of pain and he felt certain that his original discomfort was due to coffee. He drank Sanka or Kaffee Hag, but had not tried coffee. He continued to play tennis and golf. He was effusive in his gratitude and felt that by giving up the use of coffee and being reassured about his heart, he had been spared a life of invalidism.

COMMENT

These two cases are examples of a small series seen in office practice. They are particularly significant because of the relatively long follow-up periods, namely nine and one-half years in one patient, six and one-half in the other. The experiment with caffeine carried out in the case of the physician demonstrated conclusively that, in this instance, discomfort was due to the caffeine content of the coffee, not to reflex digestive disturbances induced by its volatile, oily constituents. The slight changes in the form of the electrocardiogram in the second case served at first to confuse the clinical picture but proved to be a source of unnecessary concern.

The number of such cases is not large, but, in my experience, cardiac pain due to coffee is more common than that due to tobacco⁴. Tea, because it is taken weaker and, as a rule, in smaller quantities, is less frequently concerned. This type of pain occurs predominantly in persons with apparently normal hearts, discomfort caused by tobacco is more frequent in patients with diseased coronary arteries who have already experienced spontaneous attacks.

The character of the pain is different from that of the so-called

"anginal" type, in that it is not severe, is of relatively long duration and is not induced by effort or emotion. It may radiate to one or both arms, causing a sensation of heaviness or soreness. When present, it is not aggravated by exercise. The discomfort is not relieved by taking nitroglycerine. Physical examination reveals no signs of organic cardiac disease. In spite of these distinguishing features, mistaken diagnoses have been made and patients have been alarmed and restricted in their activities without good cause.

All of those whom I have seen with pain due to coffee have been high-strung, tense individuals. Several have been under mental and emotional stress, induced by such causes as economic difficulties, marital incompatibility or a heavy load of responsibility. The question may be asked as to whether they were suffering from a psychoneurotic state with cardiac symptoms. This seems unlikely, for the pain disappeared promptly after stopping the use of coffee in each instance. It is more probable that their increased susceptibility to coffee was due, in part, at least, to a lowered nervous threshold. The subsequent history of the physician (Case 1) indicates that this susceptibility may be transitory. The course of these patients has shown that they were not suffering from any serious, organic cardiac disease, coronary sclerosis, if present, has not manifested itself by symptoms or signs. The lawyer (Case 2) has so far enjoyed almost 10 years of active life and has achieved, during this period, conspicuous success in his profession.

The action of caffeine on the heart and blood vessels is both central and peripheral, varying with the amount taken. A cup of coffee or strong tea contains about 0.1 gm ($1\frac{1}{2}$ grs) of the alkaloid. The predominant action of moderate doses consists in vasodilation combined with cardiac stimulation. The heart rate is accelerated, the amplitude of cardiac contractions is increased and cardiac output is correspondingly augmented. In experimental animals, the coronary blood flow is increased. The areas of the brain which control psychic processes and the medullary centers (respiratory, vasomotor, vagus) are stimulated.

The usual effects of poisoning due to coffee are nervousness, palpitation, insomnia, headache and digestive disturbances. In susceptible persons, especially those of "nervous" disposition, these symptoms are exaggerated. Chronic caffeine poisoning causes palpitation which is sometimes associated with a cardiac arrhythmia, most frequently due to premature beats. Dyspnea may occur. Neuralgias of various sorts have also been described.⁵

Brow, Long and Beattie⁶ injected caffeine intravenously into decerebrated cats and produced extrasystoles. This result was obtained after all nerve connections to the heart were severed and the suprarenal glands were removed. They concluded that the site of action of caffeine was either on the myocardium or the sympathetic nerve endings in the heart. Dikshit,⁷ on the other hand, observed that caffeine could produce extrasystoles by an action on the hypothalamic centers.

It appears, then, that caffeine may affect the heart both by its direct effect on the cardiac muscle and nerves, and indirectly through the hypothalamus. The manner in which it causes cardiac pain cannot be explained satisfactorily until more definite information is at hand concerning the mechanisms by which painful stimuli are initiated in the heart. The fact remains that, in certain persons unduly susceptible to caffeine because of increased nervous irritability or for some other unknown reason, coffee may induce cardiac pain. To recognize the existence of this relationship is, on occasion, of practical clinical importance.

CASE REPORTS

MYXEDEMA AND DIABETES MELLITUS A CASE REPORT WITH AUTOPSY FINDINGS *

By J B CAREY, M D , F A C P , S LANE AREY, M D , and E H NORRIS, M D ,
Minneapolis, Minnesota

THE patient reported in 1930¹ as having the rare combination of myxedema and diabetes died in November 1936 of carcinoma of the bowel. An autopsy was done and the complete report of the case is herewith presented (summarized in table 2)

The number of cases in the literature is not large. Shepardson and Wever⁹ and Weinstein¹⁰ have recently added to the series and in so doing have sufficiently surveyed the literature and the subject in general. One additional case (Castex et al.) has been reported since their article appeared and a summary of the total series is given in table 1. The autopsy record herewith reported on our case is the second one in the literature, the other being that of a case of Weinstein's

† The cases reported by Gordon, Holst, Wright, Rohdenberg and one of Joslin's in 1928 are open to some question, that of Holst for instance was postoperative myxedema, not spontaneous, Gordon's cases were not well studied as to basal metabolic rate, and Wright's cases may have been only hypothyroid, although they seemed to have some of the symptoms of myxedema. One of Joslin's cases is of this same character, and in Rohdenberg's case the "diabetes" had disappeared before the onset of the myxedema. An autopsy done in this latter case showed atrophy of thyroid and hypertrophy of islands of Langerhans of the pancreas, but detailed studies of neither metabolic conditions were made during life

TABLE II

CASE REPORT

A W S, male, aged 44 years, appeared for examination June 28, 1921, complaining of weakness, aching legs and shortness of breath. He stated that in March 1920 he began to feel general malaise, was easily fatigued and had some aching of legs and dyspnea on exertion. He had been treated for pyorrhea at that time without relief of symptoms. Upon questioning, it was brought out that he had suffered from impairment of visual acuity, his mental processes were considerably retarded, and his hearing especially had become quite poor. He found it almost impossible to keep awake and would usually fall asleep anywhere if he remained in a sitting position for any length of time. He had gradually gained in weight and his flesh had become soft. He had become stooped and "round shouldered" during the past year and had experienced great difficulty in holding his head erect. His hair had become dry and had fallen out, his skin was dry, although he perspired readily. There had been some swelling of the legs from the knees down, which did not vary greatly on change of posture. His wife further stated that his pulse had become slow, being about 50 when she had counted it. The family and past history were unimportant. He had two children and his wife had had two miscarriages, both at about six weeks.

Examination revealed a dry, scaling skin, thin dry hair and scaly scalp. The face was puffy especially around the eyes, and the color was rather pale. General musculature was flabby with an increase of fat deposit at the back of the neck and on the abdomen. The pulse was slow (50 to 56), full in volume but of low tension. Respiration was also slow. As the individual was questioned, his attention wandered, his speech was slow and thick and his answers were often inaccurate when checked.

by his wife. The eyes were negative except for a drooping of the upper lids. The examination as to heart, lungs and abdomen was entirely negative. The reflexes in the extremities were sluggish. There was no true edema but a typical myxedematous palpatory sensation of the subcutaneous tissue was present. The first blood pressure reading was 108 systolic and 80 diastolic. Important laboratory findings at this original examination were: Negative urine tests, a negative blood Wassermann and a basal metabolic rate of minus 36 per cent. He was placed on 6 gr. of desiccated thyroid substance daily and his subsequent course can be readily seen by reference to table 2. There was the expected symptomatic improvement and from 1922 to 1928 he was not seen, although we corresponded with him at intervals.

During the winter of 1927 he developed symptoms of diabetes, that is, he lost weight rapidly, had great hunger, thirst and weakness. The doctor in the town to which he had moved found sugar in his urine. There was great difficulty in establishing a proper balance between diet, glycosuria and thyroid dosage. Finally in August of 1928 he returned to the clinic for examination and management. At this time he was found to be thinner than before and without any signs or symptoms which one could identify as being myxedematous except that his pulse rate was slow and his basal metabolic rate was minus 17 per cent. The blood pressure at this time was 120 systolic and 80 diastolic. Again his course can best be followed by reference to table 2.

The patient was not very cooperative, insisting upon an adequate daily food intake in order to do his work as janitor. He would not report at regular intervals for checking up but usually came when either he or his wife was worried about something.

We tried to eliminate the thyroid substance, thinking that perhaps the diabetes might be better controlled if we allowed the basal metabolic rate to drop to 10 or 15 below normal. The patient, however, had a great fear of relapsing into his previous lethargic state and insisted upon taking a small daily dose of thyroid substance. During the time when he was first found to have diabetes he had a few unfortunate insulin reactions and had developed some fear of an over-dosage of it. Perhaps due to the peculiar combination of things in this case these personal factors are not very important, but they are recorded as a possible explanation for the difficulty in controlling the diabetic factor. If the basal metabolic rate had been allowed to drop below normal, and if the patient would have consented to either limiting his food intake or increasing his insulin dosage, perhaps the balance could have been better maintained.

He was, however, checked at intervals with results recorded upon the accompanying chart. It will be noted that his weight fluctuated slightly, and that his fasting blood sugar tended to remain at a higher level from 1930 on. The insulin dosage was varied from time to time by his wife, according to her ideas of his needs based upon an occasional examination of urine with Benedict's solution and the occurrence of mild insulin reactions. He complained frequently of cramping pain in his legs. His blood pressure on March 31, 1930, was 132 systolic and 78 diastolic and an electrocardiogram was normal in all leads (figure 1).

In September 1931 he suffered from an infection of the leg resulting from a varicose ulcer. During this time his wife reported the occurrence of much more sugar in the urine, so instead of modifying his diabetic program she eliminated the thyroid entirely until the infection healed—a period of about six weeks.

In December 1933 he became careless with his diet and his attending physician had to rescue him from an impending coma by the use of 200 units of insulin over a 24-hour period. Shortly after this he came to the clinic for examination, which resulted in the data noted under date of January 5, 1934 (table 2). In addition to these findings his sugar and insulin tolerance were studied by making blood sugar deter-

minations throughout the day on his regular routine The results of this study were as follows

9 30 a m Fasting blood sugar 654 mg per cent
20 units insulin administered and breakfast of approximately 24 gm protein, 47 gm fat and 78 gm carbohydrates

11 00 a m Blood sugar 562 mg per cent
11 30 a m Blood sugar 526 mg per cent
12 30 a m Blood sugar 421 mg per cent
20 units of insulin administered and lunch of approximately 26 gm protein, 42 gm fat and 18 gm carbohydrates

3 00 p m Blood sugar 171 mg per cent
4 30 p m Blood sugar 75 mg per cent

At this reading a feeling of weakness, some sweating and slight tremor were noted, so he ate his supper early and returned home

Fig 1 Normal electrocardiogram (see text)

He was advised to discontinue his daily grain of thyroid, to adhere more strictly to his diet (which he still insisted must be adequate and which was of the approximate values shown on the chart), and to use insulin units 40-10-5 daily

On July 22, 1935, he was brought into the hospital with a greatly distended abdomen. His bowels had not moved for several days and intestinal obstruction was suspected. His urine showed four plus sugar, acetone and diacetic acid. His breath was acidotic and his blood sugar was 770 mg per cent. He was given 140 units of insulin with glucose together with colon irrigation, and over a period of 48 hours his acidosis cleared up and his urine became sugar free and also the supposed bowel obstruction was apparently relieved. At least the enemata brought away large amounts of fecal material and gas and the abdominal distention decreased. Previous to this he had been using about 45 units of insulin daily. He was discharged from the hospital without further bowel study and returned to his former program of diet, insulin and thyroid daily. His attending physician reported that from that time until the final events he had several attacks of abdominal distention relieved by enemata. After each such incident, however, his abdomen remained somewhat more distended than before. His bowels were usually constipated but with occasional attacks of diarrhea. The most violent of these attacks were in February and July 1936 and these were accompanied by coma. There was no vomiting at any time and very little pain. Finally about November 10, 1936, he showed signs of obstruction with enormous abdominal distention, this time not relieved by enemata or abdominal stupes. He became progressively weaker and finally died November 16, 1936. The autopsy was performed within five hours of death by Dr E H Norris, whose record of the autopsy is as follows

"The body is that of a well-developed white man, 185 cm long, weighing about 170 lbs. The face, shoulders, arms, forearms and hands are extremely emaciated. The veins of the arms and shoulder regions stand out prominently. There is huge distention of the abdomen, the highest point above the table being 38 cm. There is marked edema of the lower extremities below Poupart's ligaments, a bit more marked on the left than on the right. There is tremendous edema of the scrotum and penis. Rigor is not present. Hypostasis is evident over the posterior parts, no cyanosis or jaundice. The pupils are 6 mm in diameter.

"Upon incising the skin of the abdomen the edges retract spontaneously so that they are separated by a distance of 15 cm before the peritoneum was incised. The peritoneal cavity contains about 500 c c of clear straw-colored fluid. The diaphragm reaches the third interspace on the right, the fourth rib on the left. The colon is hugely dilated from a point about 30 cm proximal to the anus, where a firm small annular carcinoma apparently occludes the bowel. The dilated portion of the colon measures 42 cm in circumference, the entire length of the colon, including the portion distal to the carcinoma, is 200 cm. There is moderate edema and slight dilatation of the lowest portion of the ileum. A large Meckel's diverticulum is present. The appendix is atrophic and presents as a white cord.

"The left pleural cavity has no adhesions, contains 200 c c of clear fluid. The right cavity is obliterated by firm adhesions. The pericardial sac contains about 40 c c of clear fluid and no adhesions.

"The heart weighs 250 grams. There is one white soldier spot on the left ventricle. There is no lesion on the valvular or mural endocardium. The musculature is of normal consistence, brown in color and shows no gross fibrosis. The coronary vessels are patent at their orifices, along their trunks they show grade I atherosclerosis with some thickening and slight narrowing of the lumina.

"The right lung weighs 400 grams, the left 220 grams. There is crepitation throughout both lungs but slightly diminished in both. The cut surfaces yield almost no fluid and no pus. The lungs appear drier than normal.

"The spleen weighs 75 grams. Its capsule is wrinkled. The pulp appears

fibrous and a number of small white nodules are scattered through it. The nodules vary from 2 to 6 mm in diameter.

"The liver weighs 1300 grams. The capsule is smooth. Two areas of infiltrating tumor are seen through the capsule. On section several other white areas of infiltration are noted. These metastatic lesions are not large or extensive, the largest is about 5 cm in diameter. The parenchyma of the liver is lighter in color than normal. A yellow cast is apparent and the general tone might be described as dark tan. The lobular markings are not clearly recognizable. The gall-bladder is markedly distended with thin dark bile, no concretions.

"The stomach, duodenum and small intestine are essentially normal, except as noted above. There is a small firm polypoid nodule projecting from the surface of the stomach about 1 cm proximal to the pyloric ring.

"The pancreas weighs 55 grams. It is small and atrophic, the atrophy seems to be general but perhaps is most marked in the head portion. Microscopically the acinous and islet tissues appear normal morphologically. There is no increase in the fibrous stroma. The impression is strong, however, that there may be fewer islands in the tail region of the gland than is normal. The right adrenal weighs 6 grams, the left 6.5 grams. They appear normal.

"The right kidney weighs 130 grams, the left 160 grams. The capsules strip with ease, leaving smooth surfaces. The cut surfaces show no lesions. There is moderate dilatation of the right ureter, extending from the bladder to the region of the pelvic brim. The bladder shows no gross lesion. The prostate is small. The seminal vesicles, epididymides and testes show no gross lesions.

"The root of the aorta and the thoracic and abdominal portions show grade I atherosclerosis. A number of raised oval plaques are noted but there is no ulceration and no evident calcification.

FIG 2 Microscopic section of thyroid gland (See text for description)

"The organs of the neck are studied after removal of the larynx. The thyroid gland is scarcely recognizable, no normal thyroid tissue is apparent. The organ can be identified by the form and distribution of such tissue as is present, which is yel-

lowish white, very soft and flabby Both lateral lobes, the isthmus and the pyramidal lobe can be recognized after careful dissection The microscopic findings of the sections of the thyroid gland tissue showed almost complete replacement of the follicular parenchyma by collagenous fibrous tissue In a few scattered areas greatly distorted epithelial structures can be found (Figure 2) Four parathyroids are recovered and appear to be normal

"The lymph nodes of the mesentery and those around the celiac axis and pancreas are bright yellow and soft The reticulo-endothelial cells of the mesenteric nodes show large amounts of neutral fat and lipoids The hilar nodes in the mediastinum are anthracotic and contain similar tissue, no other change

"The brain shows no gross lesion The vessels at the base show no sclerosis The hypophysis and pineal gland are grossly normal

"There is only a very small amount of fat present in the subcutaneous tissue, in the mesentery and in other parts where fat might normally be found

Diagnoses 1 Atrophy of the thyroid and pancreas 2 Huge megacolon 3 Carcinoma of the sigmoid with metastases to the liver 4 Myxedema (clinical) 5 Diabetes mellitus (clinical) "

A complete discussion of the various aspects of this association of myxedema and diabetes will be found in the papers of Shepardson and Wever,⁹ Weinstein¹⁰ and of one of us¹ Others^{11, 6, 2, 5, 3, 7, 4, 8} have also commented upon the effect of hyper- and hypothyroid states on carbohydrate metabolism Although the occurrence of myxedema and diabetes in the same patient is probably wholly fortuitous, there seems to be no doubt that, once established, there is a reciprocal reaction of the secretions of the two glands concerned It is not apparent that the diabetes influences the myxedema, but it is certainly evident that the myxedema modifies the diabetes That is, whenever the metabolic rate is increased by the administration of thyroid, the carbohydrate tolerance is markedly reduced In spite of this, of the two recorded deaths neither was due to either diabetes or to the effects of myxedema In Weinstein's case death was said to be due to heart failure of congestive type, and at post mortem high grade arteriosclerotic aortic valvular disease was found—apparently not a myxedema heart, although no other details of the pathological examinations of the cardiovascular system were given Our case died of intestinal obstruction

COARCTATION OF THE AORTA, DISSECTING ANEURYSM, AND ANEURYSMAL DILATATION OF THE LEFT VERTEBRAL ARTERY, REPORT OF A CASE *

By LINN J BOYD, M D, F A C P, and S CHARLES WERBLOW, M D,
New York, N Y

ALTHOUGH several unusual, indeed, almost unique features alone justify the publication of this case, a more compelling motive, the equally rare correct appraisal of the situation, is responsible. Only 10 per cent of the cases of aortic coarctation have been recognized ante mortem and its discovery at postmortem examination remains a "surprise d'amphitheatre". One of us (L J B) has had the opportunity to make the presumptive diagnosis of coarctation of the aorta twice within two years on the basis of hypertension, marked differences in the blood pressures in the arms and legs, notching of the lower borders of the ribs and absence of the aortic arc with dilatation of the ascending aorta. However, the coarctation was completely unsuspected in the present case.

The same general situation prevails in respect to dissecting aneurysm. Less than 5 per cent of the reported cases have been recognized ante mortem. The typical features of this case permitted belated but ante mortem recognition. The combination of coarctation of the aorta and rupture (or dissecting aneurysm) is evident in 16 per cent of the cases of isthmus stenosis reported in the literature.

Since the circulation for the lower half of the body is derived almost entirely from the subclavians in aortic coarctation, it is not surprising that the vertebral arteries, representing the first subclavian branches and participating in the formation of collateral circulation, should become elongated and dilated. However, distinct aneurysmal dilatation of one vertebral artery, sufficient to induce partial pressure atrophy of the cerebellum, as occurred in this case, is extremely unusual. While this dilatation probably represented an associated vascular anomaly, it did not occur at the bifurcation of a vessel and did not represent a "congenital military aneurysm" whose rupture accounts for the hemiplegia.

A brief résumé of the significant points follows.

CASE REPORT

A C, a 57 year old housewife, entered the Metropolitan Hospital October 8, 1936, at 8 30 p m, complaining of weakness and of very intense pain in the right abdomen and right kidney region.

* Received for publication December 30, 1936.

From the Department of Medicine, The New York Medical College and Flower Hospital and the Medical Service of the Metropolitan Hospital, New York City.

Four years before she had experienced a very severe epistaxis. At that time her physician discovered hypertension. Dyspnea on exertion, edema of the ankles at night, and nocturia two to three times have been noted during the last two years. Menopause occurred 13 years ago, venereal infections were denied. No pregnancies.

One week prior to admission while doing housework, she was suddenly seized with excruciating pain in the right lumbar region. This pain radiated downwards. At the same time she noted severe precordial pain, a choking sensation in the neck, and these were accompanied by vomiting. In a few hours the choking sensation and vomiting ceased but the pain and weakness persisted. She applied mustard plasters to the back and chest for the relief of pain but without success.

Examination The patient was a well developed obese white female lying in bed apparently in pain. Slight cyanosis of the lips and tip of the nose was observed. Neither dyspnea nor orthopnea was evident. Over the left lower anterior chest and over the entire lumbar region there was a large first degree burn (mustard plasters).

Head No scars, deformities, nor abnormalities. *Eyes* Pupils equal and react to light and accommodation. No nystagmus, strabismus nor disturbance of extraocular muscle movements. The arteries of the fundi are sclerotic, but no hemorrhages are present. *Nose* Septum deviated to the right. Mucous membranes normal. *Mouth* Teeth stained and carious, tongue coated, throat moderately injected.

Chest Breasts large and pendulous but no masses. Chest expansion free and equal, no abnormal pulsations, lungs negative. *Heart* PMI in the sixth interspace at the anterior axillary line. No murmurs or thrills elicited. The aortic second sound was accentuated. The cardiac rhythm was regular, rate 100. The heart sounds were distant. The radial pulses were equal, synchronous, and regular, blood pressure 180 systolic and 120 diastolic in both arms.

Abdomen No viscera could be palpated and there was no evidence of free fluid. No tenderness, rigidity or masses. *Back* Marked tenderness in both lumbar regions, otherwise negative.

Extremities No edema or clubbing, the normal reflexes were present and no pathological reflexes could be elicited.

Impression On admission she was regarded as an instance of hypertensive cardiovascular renal disease developing upon an arteriosclerotic basis with probable renal arteriolar sclerosis. It was thought that she should be regarded as a hypertensive angina pectoris rather than a coronary infarction in view of the maintenance of the high blood pressure level. Lumbar radiation of pain in coronary infarction has not been encountered by the writers and suggested a renal lesion, possibly nephrolithiasis. As liberal amounts of morphine scarcely blunted the pain it was decided to defer further investigation until the patient was more comfortable.

Throughout the following day the pain was less severe. Blood chemical tests were normal. The blood Wassermann test was three plus. The white blood cell count was 13,200 with 80 per cent polymorphonuclears. In view of the evident improvement it seemed advisable to postpone electrocardiographic examination.

At 8 00 p m that night she again complained severely of intense aching pain in the lumbar region and severe aching pain in both sides of the chest. The blood pressures remained unchanged. At 11 00 p m the patient became stuporous and was unable to speak. There was constant moaning, and rubbing of the lumbar region with her right hand. Respirations were rapid and shallow. The face was pale and the body covered with cold sweat. Soon there appeared a complete paralysis of the left arm, leg, and face. The pupils were equal but the right reacted poorly to light. Within a few minutes no pulse could be felt at the left wrist and no blood pressure could be obtained in this arm. The blood pressure on the right arm was now 200 systolic and 75 diastolic and the pulse was full and regular. On the basis of the

symptomatology now present a presumptive diagnosis of dissecting aneurysm was suggested (Dr Carl Nussbaum) At 12 30 p m she had a generalized convulsion and died

An abbreviated account of the post mortem follows (courtesy of Dr Andrea Saccone)

The body is that of a well developed white adult female Rigor mortis is complete, livor mortis present posteriorly The hair is grey The pupils are equal, regular and in mid-dilatation Lips, finger tips and toes are cyanotic A large erythematous area is noted over the entire lumbar region

FIG 1 The coarctation may be seen at the upper right of the illustration (A) The large vessels of the arch, normal in number and arrangement but enlarged owing to their participation in the formation of anastomoses, are evident just to the left of the coarctation The atheromatous patches in the intima can also be identified Proceeding to the left is the longitudinal tear in the aorta (B), below this, two of the aortic cusps are visible (This illustration became available through the courtesy of the Medical Examiner's Office, New York City The specimen has been placed in the museum of that department)

On mid-section the subcutaneous fat measures $1\frac{1}{2}$ cm in thickness There is no free fluid either in the abdominal or pleural cavities The pericardium contains 300 c c of blood, most of which is clotted and envelops the heart

The epicardium is infiltrated with a moderate amount of fat The coronary vessels are tortuous The right heart is soft, the left firm The muscle of the right

ventricle measures 3 mm in diameter while that of the left ventricle is $1\frac{1}{2}$ cm in thickness. There is some hardness at the base of the aortic valve but its cusps are normal in number, size and arrangement. The orifices of the coronary vessels are normal. About 2.5 cm above the line of closure of the aortic valves there is a longitudinal tear in the intrapericardial portion of the ascending aorta. This tear extends through the aorta and is the source of the blood in the pericardial cavity. The entire aorta, the branches of the arch and both iliac arteries have been dissected by a large accumulation of blood between the intima (?) and media. The innominate, carotid and left subclavian are very large and branches of the left subclavian are particularly enlarged and show well developed anastomoses. No anomalous branches from the aorta were noted. The intima is covered by many scattered atheromatous patches. At the isthmus of the aorta, just at the ligamentum arteriosus, there is a decided narrowing of the lumen by a firm ring-like thickening so that the lumen of the aorta at this point will just admit a lead pencil. The diameter of the aorta above the coarctation is considerably greater than the diameter below. The mitral and tricuspid valves are normal. Both auricular appendages are clear. The myocardium is uniformly dull brown in color.

The right lung is soft in consistency and dark in color. On section some bloody fluid oozes from the cut surface. The left lung is similar. The gall-bladder is filled with a small amount of thin bile. The liver cuts easily and shows a moderate nutmeg appearance. The splenic capsule is wrinkled and the pulp soft. The pancreatic parenchyma shows congestion. The duodenum is edematous and the remainder of the intestine reveals congestion. The adrenals are separated into two layers by edematous hemorrhagic fluid. The kidney capsule strips easily leaving a granular surface with prominence of the stellate veins. The markings are lost. The cortex is narrow and irregular and the entire parenchyma markedly congested. Uterus and adnexa are normal. The bladder mucosa is congested.

Some thickening of the bone is noted upon removal of the calvarium. The dura as well as the leptomeninges is markedly congested. There is moderate cloudiness of the sulci. The left vertebral artery is markedly dilated and tortuous and forms a short fusiform dilatation, $1\frac{1}{2}$ cm in diameter. The inferior surface of the left cerebellar hemisphere is correspondingly indented by the dilatation of this vessel. The cerebellum is asymmetric and the right vertebral artery is thinner than the left. The left lateral ventricle is slightly enlarged, no change at the base of the fourth ventricle or in pons. The remainder of the brain reveals a lacunar stage of cerebral arteriosclerosis with lesions located principally in the gray nuclei of the right hemisphere.

Anatomical Diagnosis Hemopericardium, rupture of the aorta, dissecting aneurysm of the aorta, branches of the arch and iliac arteries, coarctation of the aorta, fusiform dilatation of the terminal portion of the left vertebral artery, generalized arteriosclerosis, pressure atrophy of the inferior surface of the left cerebellar hemisphere, passive congestion of the lungs, cloudy swelling of the liver, passive congestion of the spleen, chronic diffuse nephritis with terminal congestion, congestion of brain.

Upon microscopic examination of the aorta with special reference to the vasa vasorum no evidence of syphilis or other lesion could be found. The intima was dissected and degenerated near the tear with an adherent clot of fibrin, elsewhere it is thrown into irregular folds. Near the tear the elastic membrane is completely torn and there is a faint necrosis of the media which elsewhere merely shows dissection. The adventitia is negative. Examination of the kidney sections shows a chronic glomerular nephritis with terminal nephrosis.

COMMENT

If coarctation of the aorta had been suspected it is probable that a marked difference in the blood pressures of the arms and leg would have been found. However, less than 3 per cent of the reported instances of coarctation, in itself an uncommon anomaly, have been found in females over 50 years of age. Apparently the oldest age of rupture of the aorta associated with coarctation in a female hitherto reported was thirty. Moreover if persistent differences in the arm blood pressures had been found early in this case, we would have been inclined to attribute them to a specific mesaortitis.

Inexplicable hypertension in youths is extremely suggestive of coarctation, apparently this possibility must be considered, even if rarely, in older individuals. It is often stated that glomerular nephritis must be eliminated as a cause of hypertension in suspected coarctation, in this case both lesions existed. If the dissection of the renal arteries and a more protracted course had permitted, uremia might have further complicated the puzzling picture.

Among the signs commonly attributed to coarctation the following were absent in this case: disproportion in size, color, and temperature between the upper and lower half of the body, abnormal pulsations in the neck, back and intercostal vessels, palpable intercostal arteries, parasternal post-systolic murmur. Notching of the lower border of the ribs was not studied by roentgen-ray, but none was found at post mortem. The intercostal vessels did not play an important rôle in the anastomosis. Dilatation of the ascending portion of the aorta would have been found on roentgen-ray but we would probably have attributed it to a non-existent luetic aortitis. Absence of the aortic arc in the second left oblique position ought to have been present. Other signs such as retardation or diminution of the femoral pulse, small oscillometric waves, increased reactive hyperemia in the poorly circulated extremities, the low fall and later, long duration of increased superficial temperature during and after obstruction to the circulation, the long duration of the fall of blood pressure in the lower limbs after application of obstruction to circulation in the upper half of the body would have been equivocal in the presence of dissecting aneurysm.

In retrospect our diagnostic failure may be assigned chiefly to two prevalent mistakes. Our neglect to determine blood pressures in the upper and lower extremities routinely in cases of hypertension, our failure to think of the possible presence of an unusual lesion.

The symptomatology of the dissecting aneurysm in this case was typical. The immediate onset of maximum and severe pain, its unusual radiation (or localization) to below the mid-lumbar region, the nausea and vomiting (aortic depressor nerve?), the maintenance of the high level of blood pressure with regular scarcely elevated heart rate, the development of hemiplegia and the absence of pulse in one arm may be mentioned in passing. The persistent and recurring back pain may be attributed to marked dissection of the intercostal arteries. Supra-pubic cyanosis, said to be present in aortic obstruction at the bifurcation and arising from a "rider" embolus, was absent.

Hemiplegia occurs not infrequently in coarctation of the aorta as the result of cerebral hemorrhage. This may be due to rupture of an intracranial "congenital aneurysm." In this case the hemiplegia may be attributed partly to the occlusion of one carotid artery by the dissection of its walls, partly to the cerebral

edema. Partial or complete disappearance of the carotid pulsation ought to have been elicited in this case but on this point the record is silent.

A careful study of the vasa vasorum failed to reveal any evidence tending to incriminate syphilis as a factor in producing the dissecting aneurysm. Nevertheless it may have facilitated the evolution of the catastrophe. Evidence was also lacking of a *mesaortitis dissecans* in the sense of Babes and Mironescu. The medial changes of Gsell and Erdheim's *medionecrosis aortae idiopathica cystica* were likewise absent. The minute hemorrhages from the vasa vasorum and small mural hematoma described by Moriani were not present. The thinned and faintly staining media together with the fragmented and broken elastic membrane are consistent with the mechanically conditioned transformation of the aortic wall in the presence of persistent hypertension (as described by Einhauser). It does not seem logical to speak of a constitutionally weak aorta when it resisted the onslaught of hypertension for more than one half a century. It is of interest to note that the aortic tear occurred at Oppenheim's point of maximum functional strain of the aorta. In contrast to most cases the tear was longitudinal rather than transverse. This is alleged to facilitate hemopericardium rather than extensive dissection. The presence of concomitant vascular anomalies of constitutional origin is strongly suggested by the aneurysmal dilatation of *one* vertebral artery.

Finally increasingly distant heart sounds with maintenance of the blood pressure in a case of dissecting aneurysm (or coarctation) should justify the diagnosis of hemopericardium even in the absence of increased cardiac dullness. The absence of cardiac hypertrophy and dilatation in the presence of prolonged hypertension, as in this case, should be provocative of thought.

SUMMARY

A case of the adult type of coarctation of the aorta, dissecting aneurysm and fusiform dilatation of the left vertebral artery is presented. Attention is directed to our failure to recognize the coarctation rather than our success in appraising the dissecting aneurysm. Diagnostic errors occur in both lesions with disturbing frequency which may be diminished by popularizing consideration of these lesions as diagnostic possibilities.

EDITORIAL

THE VALUE TO CLINICAL MEDICINE OF EXPERIMENTAL STUDIES ON THE LIVER

It is difficult for the clinician interested in hepatic disease to overestimate the debt owing to laboratory workers who have so diligently studied the pathologic physiology of the liver. Clinical knowledge of hepatic disease, having been almost at a standstill for fifty years, is now being immensely enriched by the contributions of physiologists and biological chemists who have, first, fully informed us of the functions of the liver and later demonstrated its reparative and regenerative properties, its extraordinary reserve functional capacity and, most recently, the activities of the organ in maintaining normal internal environment.

A large part of the success attained by the physiologists has been attributable to their ability to reproduce in the experimental animal two of the common clinical affections, obstructive jaundice and parenchymatous injury. The pathology and physiology of the former condition, easily produced by ligation of the bile ducts, has now been thoroughly studied from its inception to its end stage of obstructive biliary cirrhosis. The simulation of parenchymatous lesions has been a more difficult matter but it is now possible to reproduce an almost perfect experimental counterpart of atrophic cirrhosis by the continued administration of carbon tetrachloride. The effects of variations in the diet on the course of experimental hepatic disease, and on the ability of the liver to repair itself and regain its function after an almost lethal injury have been fully demonstrated by this means.

The protective effect of high carbohydrate diets in poisoning from chloroform and phosphorus, first shown years ago by Opie and Alford,¹ is now known to be equally effective in retarding the development of hepatic damage induced by biliary obstruction and carbon tetrachloride. Diets of high fat content recently have been shown by Bollman² to have an opposite effect. For instance, it is virtually impossible to produce any significant hepatic lesion in the dog by administration of alcohol if the animal is on a mixed diet, with a high fat diet marked fatty degeneration can be produced by this means. Such a diet given alone, without any hepatotoxic agent, also will lead eventually to fatty metamorphosis. Such fatty livers are easily injured by any hepatic poison and undergo necrosis and parenchymatous degeneration even with minimal insults. The only known means of protection against the fatty change produced by dietary means and by certain specific poisons are three: an increased intake of carbohydrate, the adminis-

¹ OPIE, E. L., and ALFORD, L. B. The influence of diet upon necrosis caused by hepatic and renal poisons. I. Diet and the hepatic lesions of chloroform, phosphorus, or alcohol, *Jr. Exper. Med.*, 1915, **xxi**, 1-20.

tration of lecithin or one of its components, choline, and the use of a pancreatic hormone designated as "lipocair" by its discoverer, Dragstedt³ and his associates

The relation of the last two mentioned substances to fatty change in the liver is an interesting chapter in itself. The development of hepatic insufficiency in pancreatectomized dogs whose diabetes was controlled by insulin led to an investigation of the morphology of the liver, it was first shown by MacLeod and his collaborators⁴ and later by Best, Ferguson and Hershey⁵ that the underlying lesion was marked fatty degeneration. Similar changes in the hepatic parenchyma are known to occur in the diabetic human subject⁶ and in patients with pancreatic atrophy produced by lithiasis. In the pancreatectomized dog, lecithin or choline has been shown to exert an inhibitory effect on this process, recently Dragstedt and his associates³ have shown that it is possible to extract from the pancreas a hormonal substance which inhibits deposition of fat in the liver after pancreatectomy. This preparation has been used effectively in treatment of one human subject with pancreatic stone and a presumably fatty liver and may have some further clinical application in severe diabetes and in acute fatty infiltration of the liver produced by poisons.

Do these fatty changes constitute the forerunners of nodular cirrhosis? Ordinarily they do not lead to any permanent hepatic lesion in the experimental animal but knowing the extreme vulnerability of the fatty liver, it is reasonable to assume that any added toxic factor might easily lead to the development of parenchymatous degeneration and nodular hyperplasia. It is clear that more attention will have to be paid to the relation of the diet to hepatic disease and that regulation of its fat and lecithin content may well find a place in the therapeutics of hepatic disease.

From the chemical and physiologic laboratories some light has been cast in recent years on the mechanisms by which ascites is produced. It has been demonstrated that the condition does not depend on portal back pressure alone, although in most hepatic diseases associated with ascites there are gross evidences of interference with portal blood flow. Ascites sometimes appears spontaneously as a terminal development in the animal with long-continued experimental biliary obstruction and in such animals may be induced almost at will by oral administration of meat extractives which are virtually free of protein. The same situation exists in animals with cirrhosis induced by carbon tetrachloride but in neither instance is there any satisfactory explanation of why these innocuous meat extracts have this puzzling effect. The spontaneous appearance of fluid, on the other hand, is

thought to depend on at least three factors, the degree of parenchymatous hepatic injury, interference with portal circulation and reduction of plasma proteins. A slight but progressive fall in concentration of these last-named substances occurs almost as a rule in hepatic disease of any type, both experimental and clinical and, more significantly, there is a proportionately greater fall in serum albumin than in total protein, the globulin fraction may be either normal, increased, or decreased. Without entering into detailed discussion of the reasons for this development of hypoproteinemia, it may be said that the available evidence points to failure of the liver to furnish albumin or albumin-producing substances, with a disturbance in the dynamic equilibrium existing between stored and circulating protein.⁷ The obvious result is a fall in the colloid osmotic pressure of serum, a condition which favors transudation in regions of venous stasis. The full extent of this decrease in the osmotic properties of serum of patients with hepatic disease has only recently been appreciated. Butt and Keys⁸ have measured the colloid osmotic pressure by a modification of the method in which a membrane bag is used and have shown reductions to as little as half of the normal value, the observed pressures of practically all patients with ascites or edema are below the theoretical level at which transudation may occur. Furthermore, the figures of the named investigators show clearly that the observed osmotic pressure is not in linear relation to the total protein content of serum and that in about a third of the cases, sharp reductions in colloid osmotic pressure are noted even when the value for total protein is normal. Bollman's⁹ unpublished studies on the effects of plasmapheresis in animals with experimental cirrhosis have in general confirmed the above-mentioned observations, but they appear to show that there is no constant level of colloid osmotic pressure at which ascites invariably occurs. In other words, there are other variable factors presumably involving such matters as pressure in mesenteric capillaries and the degree of hepatic damage. The effects of meat extracts described in an earlier paragraph may involve such factors. Measurements of pressure in the portal system of subjects with cirrhosis are not as yet available, but such studies doubtless will be undertaken by physiologists, in the experimental animal. The problem of electrolyte and water distribution between circulating fluids and tissue fluids must also be investigated further since changes in osmotic pressure of the order of magnitude observed by Butt and Keys can scarcely be without some effect on the hydration and electrolyte content of individual cells.

Some of the major clinical problems yet to be solved by students of hepatic disease are concerned with the nature of hepatic insufficiency and with the cause of the hemorrhagic diathesis. On the first matter little information is available although the metabolic disturbances which occur in

⁹ BOLLMAN, J. L. Unpublished data.

hepatectomized animals and in those with extreme hepatic injury have been extensively studied. One fact is certain, no form of hepatic damage, clinical or experimental, even approximates the picture of absolute hepatic insufficiency produced by total removal of the liver. The major metabolic properties are almost universally preserved even with maximal hepatocellular destruction. The most favored hypothesis of clinical hepatic insufficiency is that the detoxifying function of the organ is so altered that the increased susceptibility to endogenous and exogenous toxins produces a fatal issue before the entire function of the liver is lost.² The vulnerability of the damaged liver to infections, anesthetics, and hepatotoxins may be cited in support of this hypothesis, as well as the fact that the symptoms of the Eck fistula animal seem to be clearly attributable not so much to diversion of blood flow as to failure of detoxification. In addition to the hypothetical failure of this function, one must concede that other factors enter into the clinical picture of hepatic insufficiency. In the occasional case there are striking changes in the chloride content of blood and in the acid-base equilibrium, the factor of anoxic anoxemia which is quite constantly present in advanced hepatic disease also may not be without significant effect especially on those tissues which are particularly sensitive to oxygen want. There is good reason to believe that the condition of hepatic insufficiency is a reversible one, and the occasional recovery of a patient from profound hepatic coma gives hope that its physiologic nature may be known and controlled.

So far as the problem of hemorrhage in hepatic disease is concerned, it seems to be one manifestation of hepatic insufficiency, or at least the two often occur simultaneously. All factors necessary for normal coagulation of blood such as calcium, fibrinogen and thromboplastin are presumably present in normal amounts, leaving prothrombin as the only variable. Exact methods for the determination of these substances have not been developed but studies from a number of laboratories indicate that the hemorrhagic state in hepatic disease may depend on deficiency of prothrombin alone¹⁰ and that this in turn may be dependent on the exclusion of bile from the alimentary tract or on disruption of the mechanism by which prothrombin or some precursor is stored.

The possible relation of prothrombin to the hypothetical "Koagulations vitamin," the existence of which has been only recently recognized, was first brought under consideration by biochemical studies of the diseases of domestic animals. In such widely differing conditions as a specific deficiency disease of chicks, the toxic sweet-clover disease of cattle, prolonged obstructive jaundice and complete external biliary fistula, the prothrombin of the blood is reduced. Since the first two conditions respond to administration of vitamin K, it is reasonable to hope that the last two may be similarly affected. Chemically, prothrombin and vitamin K appear to have

¹⁰ QUICK, A. J., STANLEY-BROWN, MARGARET, and BANCROFT, F. W. Study of coagulation defect in hemophilia and in jaundice, *Am. Jr. Med. Sci.*, 1935, CXC, 501-511.

little in common, but there is indirect evidence pointing to some obscure interrelation between the two substances. Clinical data are almost completely lacking but the theoretical possibilities are exceedingly attractive.

Certain other fields of purely clinical research in hepatic and biliary disease which are being developed can only be mentioned here. Studies on the so-called biliary dyskinesia to which Westphal,¹¹ Ivy^{12, 13} and McGowan¹⁴ and his collaborators have contributed are furnishing an explanation of some hitherto obscure visceromotor phenomena as well as helping to explain the mechanism of the sphincter of the common duct and its relation to biliary pain.

The application of accurate physiologic methods to the clinical study of hepatic and biliary disease obviously is increasing our comprehension of the subject, but it is apparent that many crucial problems will have to be solved, not at the bedside alone but by the clinician and the experimental pathologist working in cooperation. The clinical application of facts already known and of others yet to be unearthed doubtless will be a slow process but it is equally certain that their utilization eventually will serve to expand present diagnostic and therapeutic horizons. Just as we owe our present facilities for the care of the diabetic patient to studies on the dog, so we may eventually attain some mastery of hepatic disease by continuation of experimental studies which at first seem far removed from the field of clinical medicine.

REVIEWS

Observations of a General Practitioner By WILLIAM N. MACARTNEY, M.D. 478 pages, 21 × 15 cm. The Gorham Press, Boston. 1932. Price, \$3.00.

Physicians actively engaged in the practice of medicine will like this salty volume with its first hand observations on disease and human beings interspersed with humorous anecdotes of varying degrees of savoriness. Those who are hospital physicians will be interested in the different types of disease seen in practice. There is much to think about in these chapters for the author includes his medical philosophy as well as his medical experience. He writes in vigorous and pungent short sentences and says his mind plainly. Therapy is particularly worth consideration because one feels he applied it himself and observed the results personally without an intervening screen of assistants, interns and nurses.

Altogether this is an entertaining and instructive book. Most of us will heartily disagree with a large number of the author's ideas but we will think all of them worth considering and tuck many a suggestion away in our mind for future trial.

M C P

Der Blutdruck Des Menschen By ESKIL KYLIN. 322 pages, 23.5 × 16 cm. Verlag von Theodor Steinkopff, Dresden and Leipzig. 1937. Price, RM 24.

The purpose of this book is to present the author's views as to the problem of abnormalities of blood pressure. It is therefore a discussion of the mechanisms involved in the maintenance of normal pressure and in the causation of hypertension and hypotension. It is not concerned except in a secondary way with the symptomatology of blood pressure derangements nor with therapeutic procedures. The first section deals with normal blood pressure, arterial, capillary and venous. This is followed by a very interesting discussion of modern concepts of blood pressure regulation, divided into chapters on central factors in blood pressure regulation, on peripheral mechanisms, and on the role of endocrine organs.

The subject of arterial hypertension is introduced by a section devoted to a general discussion of the varieties of disturbances or lesions which may lead to a higher level of blood pressure. The author is a strong advocate of the belief that the hypophysis secretes through an ependymal lined canal into the third ventricle. The character of the secretion alters the irritability of hypothalamic blood pressure regulating centers, and plays therefore a major role in essential hypertension. The evidence in favor of these views is marshalled in an ingenious way. The author devotes considerable space to an attempt to minimize the relationship between kidney lesions and hypertension. It is evident that he is not well acquainted with the foreign literature since he omits the fundamental experiments of Goldblatt and the most important references on the relation of polycystic disease to hypertension.

In the discussion of major clinical varieties of hypertension the author subdivides them into capillary and arterial forms of hypertension. He believes that diffuse glomerulo-nephritis is primarily a generalized capillary disease. No convincing proof of this assertion is offered.

Enough has been said perhaps to show that this volume will interest all students of the problem of hypertension. The author is learned, original and somewhat prejudiced in favor of his own opinions. Every internist can study the results with profit.

M C P

The Cardiac Glycosides By ARTHUR STOLL, D Sc, M D 80 pages, 25 × 17 cm
Pharmaceutical Press, London 1937

This treatise comprises three lectures delivered by Professor Stoll in the College of the Pharmaceutical Society of Great Britain under the auspices of the University of London. The first of these lectures is devoted to the importance of sugars in the plant economy and the classification of glycosides including a series of definitions of terms. In this lecture also the specific glycosides of digitalis and strophanthin are discussed. Great stress is laid on the structure of the sugars isolated from the cardiac glycosides. The historical features of the chemical and clinical events of significance in the development of these compounds are referred to in a very interesting manner.

The second lecture treats of the glycosides of squill and the hydrolysis and products of hydrolytic cleavage of scillaren A. The structures of the aglycones are discussed and compared. These structures are shown to be phenanthrene derivatives and related to the bile acids, sex hormones and toad venoms. The schemes of cleavages and the complex structures of the aglycones are especially well elucidated.

In the third lecture the author discusses the digitalis glycosides with special reference to botanical species variation. Methods of extraction are critically evaluated. The cardiac principles from *digitalis purpurea*, *ambigua* and *lanata* are compared. Comprehensive studies on the extraction of Digilamid from *digitalis lanata* are described. The author concludes that this crystalline glycoside is the only chemically pure digitalis glycoside of constant constitution. Its therapeutic dose for man orally is 0.75 mg daily. It is available also for intramuscular and intravenous medication.

The style of the author is lucid and the subject matter timely.

J C K, JR

Exophthalmic Goiter and Its Medical Treatment By ISRAEL BRAM, M D Second Edition 456 pages, 25 × 17.5 cm C V Mosby Company, St Louis 1936
Price, \$6.00

In his preface to this work, the author describes it as a "treatise on the etiology, diagnosis, and principles of the medical treatment of exophthalmic goiter, based on personal experience with over 5000 cases of this disease, observed within a period of over 25 years." In a footnote, he states that this number is included within the total of approximately 16,000 goiter cases observed.

After reading the book, one is forced to the conclusion that the author has been almost miraculously successful in curing a large series of cases of exophthalmic goiter, and in a strikingly short time. Statistically, he reports only 2600 cases, so that one wonders as to the results in the remaining 2400. Apparently 90 per cent of the 2600 cases were completely cured, as they were all well after being followed for periods of from 3 to 20 years, 10 per cent had minor residual symptoms. There were, therefore, no deaths in this group. Sixty-seven per cent of the cases were discharged from treatment after six months, 17 per cent are reported as continuing their customary duties while under treatment, and another 44.9 per cent abstained from their work for three months or less.

The author feels that surgical interference is usually contraindicated, and states that indications for thyroidectomy occur in a little over 2 per cent of all patients with Graves' disease. Surgery and radiation he classifies as local measures, to be used rarely. He places great emphasis on the danger and frequent occurrence of postoperative myxedema, and gives the impression that exophthalmic goiter with myxedema is very common in patients treated by methods other than his own.

One would feel more confidence in the author's statements if there were not so many obviously weak points in the book. The illustrations, 79 in number, are limited to photographs of patients, either before, or in many cases before and after treat-

ment The absence of photographs of histological sections of the thyroid gland is surprising Disappointing, too, is the section on basal metabolism, the term "basal metabolic rate" is not defined, is not described as a measurement of heat production of the body, nor is there any discussion of methods of determination of the rate

Literature is extensively quoted, but superficially reviewed, and opinions are given without reference to the date of the article Many antiquated observations are quoted, and it is usually impossible to tell their date from the text

In the final chapter, 55 cases are reported fairly fully except that the details of treatment are omitted

In the section on treatment, quinine is emphasized as a very important drug The therapeutic value of glandular extracts is reviewed, but, again, the author frequently quotes antiquated studies, for instance, in the discussion of the use of adrenal cortical extracts In this paragraph, he advocates the oral administration of pills of glycerinated cortical extracts Later, he advocates the oral use of ovarian residue in the presence of amenorrhea in the female

On the whole the book does not appear to be a safe guide The opinions expressed are contrary to the experience of most physicians and the data furnished will not induce those with an analytic faculty to alter their views

T N C

Pediatric Dietetics By N THOMAS SAXL, M D 565 pages, 24 × 15.5 cm Lea and Febiger, Philadelphia 1937 Price, \$7.00

Various works dealing with the diets of individuals in the pediatric age, have in the past been limited mostly to infant feeding The nutritional aspects of the child over two years of age has been relegated to the domain of adult nutritional problems Dr Saxl has presented the entire subject of pediatric dietetics in a separate volume The appearance of a work of this type is timely, for to quote Dr De Sanctis in his foreword to this volume "Lay periodicals, press and radio have persistently encouraged various types of diets for adults The vast majority of these are scientifically unsound and unfortunately have been applied to children"

The subject matter of this volume has been presented in three parts, subdivided into sections Into the first part the author condenses the mechanics and chemistry of digestion during infancy Explanation of the *modus operandi* and indications for use of the various basic constituent foods are also included in this section A comprehensive summary of accepted proprietary foods is also made In addition a brief statement of the nature, source and therapeutic use of vitamins is given

Part II deals with infant feeding, a section being devoted to breast feeding and one to the artificial method

Part III deals with dietetic management of pediatric diseases Physicians interested in various conditions have collaborated with Dr Saxl in the presentation of this section To those not sufficiently familiar with metabolic processes in pathological conditions this section will clarify a number of disease processes

The appendix is composed of numerous receipts, tables of weight, height, and foods Also, incorporated is a very exhaustive bibliography

The work in its entirety is written in a uniformly easy manner Much of the material is to be counted as superfluous, and much could be shortened without destroying completeness The volume represents a needed contribution, dealing with the nutritional needs of the child in disease and health It is a useful addition to the library of the practitioner

Dr James W Sherrill (Fellow) and Dr E F F Copp (Fellow), La Jolla, Calif, one reprint,
Dr Walter H Watterson (Fellow), LaGrange, Ill, one reprint,
Dr Edward E Woldman (Associate), Cleveland, Ohio, three reprints

Grateful acknowledgment is also made of the receipt of the following directories as gifts to the College Library

- Medical Society of the State of New York, through Dr Peter Irving (Fellow), New York City—" 1937 Medical Directory of New York, New Jersey and Connecticut ",
Bureau of Medicine and Surgery, U S N—September 1, 1937, issue of the " Navy Directory "

Dr Clement R Jones (Fellow), Pittsburgh, Pa, has donated to the College Library an original copy of the ANNALS OF MEDICINE, Volume I, No 1, April, 1920 This was the first issue of the first journal sponsored by the American College of Physicians and the American Congress on Internal Medicine, but during the intervening years and changes of administration, all official copies of this issue had disappeared It is an interesting addition to the College archives First, it is a very attractive and well-printed journal It contains the roster of the members of the American College of Physicians and of the American Congress on Internal Medicine up to March 1, 1920 In it appears the photographs of the Officers and Councilors of the College for that year, and photographs of the Convocation held on February 26, 1920, and of the Annual Banquet the same year, held at the Congress Hotel in Chicago The contents of the journal, including a comprehensive article

by the first President of the College, the late Reynold Webb Wilcox, M A, M D, LL D, D C L, F A C P, on "The Field of Internal Medicine," were made up of presentations by Louis A Turley, A M, M D, Ph D, F A C P, John A Lichty, M D, F A C P, F M Pottenger, A M, M D, LL D, F A C P, E H Reudiger, A B, M D, F A C P, Louis Faugeres Bishop, A M, M D, D Sc, F A C P, E L Tuohy, A B, M D, F A C P, F A McJunkin, A B, M D, F A C P, Hugo A Freund, A B, M D, F A C P, Bruce C Lockwood, A B, M D, and Frank Smithies, M D, Sc D, M A C P Dr Smithies was the Supervising Editor

MOTION PICTURE REELS

Mrs Louise K Smithies, widow of the late Dr Frank Smithies, former Secretary-General and former President of the College, due to Dr Smithies' long association with this College, has donated to the College Dr Smithies' two 35 mm reels showing his method of dilation of cardiospasm by the pneumatic expanding bougie These motion picture films are available, on loan, to members of the College who may wish to show them

THE TWENTY-SECOND ANNUAL SESSION OF THE COLLEGE

The Twenty-Second Annual Session of the College will be held in New York City, April 4 to 8, inclusive, 1938, with headquarters at the Waldorf-Astoria Hotel, 49th to 50th Streets, Park to Lexington Avenues Dr James H Means, of Boston, as President of the College, will have charge of the program of General Sessions and Special Lectures Dr James Alex Miller, of New York City, as General Chairman, will have charge of the program of Clinics and Round Tables

Last spring, the Executive Offices sent out a brief postal questionnaire to determine the desires of members with respect to program arrangements and items, particularly the Special Lectures, Round Tables and Clinico-Pathological Conferences

847 to 267 requested the retention of Special Lectures (these do not refer to the General Sessions, but to the series of special lectures given during the mornings, at the same time clinics are in session),

1046 to 101 favored the extension of the Round Table program,

1051 to 88 favored Clinico-Pathological Conferences on the program

Many members sent in very helpful suggestions about titles and speakers, and the Program Committee is carefully considering them

New York Hotel Rates—Hotel rates in New York City are, on the average, higher than in most other places At the Waldorf, which is one of the world's finest hotels, a special convention rate has been obtained, beginning at \$5 00 single (reduced from \$7 00), and beginning at \$7 00 double (reduced from \$9 00) In the immediate neighborhood—in fact, within one square of the Waldorf—there are several other good hotels with varying rates A list of such hotels may be obtained from the Executive Secretary of the College

The Executive Committee, composed of the chairmen of the various committees for the New York Session, is as follows Dr James Alex Miller, *General Chairman*, Dr James Ralph Scott, *Vice Chairman*, Mr E R Loveland, *Executive Secretary*, Dr Robert A Cooke, *Clinics*, Dr Russell L Cecil, *Round Tables*, Dr Howard F Shattuck, *Entertainment*, Dr Peter Irving, *Publicity*, Dr Edward P Eglee, *Local Transportation*, and Dr Willard J Denno, *Auditorium*

TESTIMONIAL TO DR POTTINGER

On September 26, 1937, former patients and friends of Dr F M Pottenger (Fellow), Monrovia, Calif, gathered in the gardens of the Pottenger Sanatorium for a dual celebration, the annual home-coming of former patients, and the celebration of Dr Pottenger's sixty-eighth birthday. More than 250 guests were present, many of whom came from points far-removed from the Pacific Coast, one from New York City.

Patients of the Pottenger Sanatorium who have been discharged as arrested or cured look upon themselves as 'alumni' and refer to their "class." The oldest alumnus present was one who had been a patient in 1903.

Appropriately inscribed, a beautiful sundial was presented to Dr Pottenger from the present patients. Other gifts were also presented and messages were received from all over the world.

Henry K Mulford, known to a host of members of the American College of Physicians as the founder of the H K Mulford Company, Philadelphia, and internationally known in the field of biological research, died during October at the age of seventy-one, after an illness of several days. Mr Mulford had more recently been the Director of the Research and Biological Laboratories of the National Drug Company, and President of the Mulford Colloid Laboratory. In connection with his early founding of the H K Mulford Company, he was directly in charge of making antitoxins and vaccines, the first in this country to interest himself in that line. He was graduated from the Philadelphia College of Pharmacy and Science in 1887.

Dr Clifford E Henry (Fellow), Minneapolis, Minn, has been advanced from the rank of commander to that of captain in the naval medical reserve corps. This rank is held by only four men in the country, and is next in line to that of rear admiral. Dr Henry is Minnesota's senior naval medical reserve officer.

The Mississippi Valley Medical Society of which Dr Harold Swanberg (Fellow), Quincy, Ill, is Secretary, offers a cash prize of \$100.00, a gold medal and a certificate of award for the best unpublished essay on a subject of interest and practical value to the general practitioner of medicine. Entrants must be ethical licensed physicians, residents of the United States and graduates of approved medical schools. The winner will be invited to present his contribution before the next annual meeting of the Mississippi Valley Medical Society (September 28 to 30, 1938), the Society reserving the exclusive right to first publish the essay in its official publication, *The Radiologic Review and Mississippi Valley Medical Journal*. Contributions shall not exceed five thousand words, shall be typewritten in English in manuscript form, submitted in five copies, and must be received not later than May 15, 1938.

Dr William B Grayson (Associate), Little Rock, Ark, was recently re-appointed state health officer for a second term of four years.

Dr William E Gardner (Fellow), Louisville, Ky, was made President-Elect of the Kentucky State Medical Association for 1937-38 at its annual meeting during September.

Dr Frank M Stites, Jr (Fellow), Louisville, was elected a Vice President. The 1938 meeting of the Association will be held in Louisville.

Dr Hubert C King (Fellow), Lakewood, Ohio, and Dr Karl D Figley (Fellow), Toledo, Ohio, are members of the subcommittee of the newly-organized Speakers' Bureau of the Ohio State Medical Association, formed for the purpose of assisting county and district medical societies in obtaining outside talent for their programs. It is anticipated that the facilities of the Bureau will later be made available for meetings of allied and lay groups.

Major General Charles R Reynolds (Fellow), Surgeon General of the U S Army, addressed the annual "Mercy Day" celebration of the Mercy Hospital in Pittsburgh on September 23, his subject being "Medicine in the Military Service"

Dr William D Stroud (Fellow and Treasurer), Philadelphia, Pa, addressed the Forty-third annual meeting of the Utah Medical Association of Salt Lake City, September 2 to 4, on "Etiology of Cardiovascular Disease, Coronary Diseases Including Angina Pectoris, Clinical Efficacy of Digitalis Preparations"

Under the presidency of Dr J Morrison Hutcheson (Fellow and Governor), Richmond, Va, the Medical Society of Virginia held its Sixty-Eighth Annual Session at Roanoke, October 12 to 14

A sectional meeting and dinner of the Fellows and Associates of the American College of Physicians was held at the Shenandoah Club in Roanoke on October 12 during the course of the State meeting. Dr J W Preston (Fellow), Roanoke, was Chairman of the local committee on arrangements for the sectional College meeting.

Dr Paul A O'Leary (Fellow), Rochester, Minn, is Secretary General of the Tenth International Congress of Dermatology and Syphilology to be held in New York City during September, 1940

Dr Warfield T Longcope (Fellow), Baltimore, Md, delivered the Gordon Wilson Lecture on "The Varieties of Hemorrhagic Nephritis and Their Prognostic Significance" before the Fifty-Fourth Annual Meeting of the American Clinical and Climatological Association in Baltimore, October 11 to 13

Under the presidency of Dr William H Cade, Jr (Associate), San Antonio, Tex, the Southern Psychiatric Association held its annual meeting at San Antonio, October 8 to 9. Among the invited guests on the program were the following: Dr George T Harding (Fellow), Columbus, Ohio—"Periodicity of the Manic-Depressive Psychoses", Dr C Charles Burlingame (Fellow), Hartford, Conn—"Can the Point of View and Technic of Private Practice Be Carried into the Mental Hospital", and Dr George R Hermann (Fellow), Galveston, Tex—"Neurocardiac and Neurocirculatory Disorders"

Dr Herman M Baker (Fellow), Evansville, Ind, will start the new year as President of the Indiana State Medical Association on January 1, 1938

Dr Hugo A Freund (Fellow), Detroit, Mich, has been appointed a member of the city Public Welfare Commission

Under the presidency of Dr George A Young (Associate), Omaha, Nebr, the Omaha Mid-West Clinical Society held its fifth annual assembly, October 17 to 22

Among the invited guest speakers were Dr William J Kerr (Fellow and President-Elect), San Francisco, Calif—"The Anxiety States in General Practice", Dr Hans H F Reese (Fellow), Madison, Wis—"The Constitution and the Biochemical Evaluation of the Nervous Patient", and Dr Thomas Parran (Fellow), Surgeon General of the U S Public Health Service—"Syphilis and the Public Health"

Dr William B Porter (Fellow) Richmond Va, was recently awarded the Jefferson Gold Medal of the Virginia Academy of Science

Dr Vincent J Dardinski (Associate), Washington, D C, has been appointed full time Pathologist and Director of the Laboratories of the Georgetown University Hospital Dr John R Cavanagh (Associate), Washington, D C, Associate Clinical Professor of Medicine at the University, will become Director of the Outpatient Department of the Hospital Dr Frank S Horvath (Associate), Associate Professor of Clinical Medicine, will be Assistant Director and Supervisor of Student Instruction in the Outpatient Department of the Hospital

Dr Russell M Wilder (Fellow), Rochester, Minn, addressed the clinical session of the New York Diabetes Association on October 15 on "Pathogenesis and Etiology of Diabetes"

Dr Nelson W Barker (Fellow), Rochester Minn, has been elected Secretary of the Southern Minnesota Medical Association

Under the presidency of Dr Charles E Sears (Fellow), Portland, Ore, the Oregon State Medical Society held its Sixty-Third Annual Session at Salem, October 21 to 23 Dr Lester R Dragstedt (Fellow), Chicago, Ill, was one of the guest speakers, his subjects being "Pathogenesis and Surgical Treatment of Duodenal Ulcer" and "Pathogenesis and Surgical Treatment of Acute Intestinal Obstruction"

Dr Louis F Bishop, Jr (Fellow), gave a talk on "Exercise in the Treatment of Chronic Cardiovascular Disease" before the Section on Medicine of the 16th Annual Scientific and Clinical Session of the American Congress of Physical Therapy on September 22, 1937, in Cincinnati

On Sunday October 2, 1937, Dr Bishop, Jr, also gave a talk (on invitation) on "Is It Safe for the Heart Patient to Fly?" before the Ninth Annual and First International Meeting of the Aero Medical Association of the United States, Hotel Waldorf Astoria, New York, October 3, 1937

REGIONAL MEETING OF MICHIGAN MEMBERS

A regional meeting of the Michigan Fellows and Associates of the College was held in Detroit, November 17, under the Governorship of Dr Henry R Carstens Dr Hugh Freund of Detroit assisted in the arrangement of the program, and the Harper Hospital acted as host Clinical presentations were given at the Harper Hospital from 4 00 to 6 30 p m, followed by a social hour and dinner Dr James D Bruce, Regent of the College, Ann Arbor, addressed the group on matters of interest about the College, and Dr A B Brower, College Governor for Ohio, Dayton, gave an address on "Hypotension" A large and representative group was present

OBITUARIES

LT COL LEROY T HOWARD

Lieutenant Colonel Leroy T Howard (Fellow), Medical Corps, U S Army, died suddenly in Washington, D C , on September 30, 1937

Colonel Howard, a native of the District of Columbia, was born October 27, 1888 He was a graduate of the Georgetown University, from which he received his medical degree in 1913 Following this he interned for one year in St Francis' Hospital, Jersey City, N J He was commissioned a First Lieutenant in the Medical Reserve Corps on September 29, 1916, and shortly thereafter he was called to active duty and pursued a course of instruction at the Army Medical School, Washington, D C , from October 14, 1916, to March 28, 1917 He was commissioned in the Regular Army as First Lieutenant, Medical Corps, on April 16, 1917, promoted to Captain March 28, 1917, Major May 27, 1918, and Lieutenant Colonel March 3, 1937 He was returned from duty in Hawaii March 29, 1937, on account of illness and was on sick leave pending retirement for disability at the time of his death

Colonel Howard was a specialist in neuro-psychiatry and served in that capacity at several of the largest hospitals in the Army During the World War he served in France He had been a Fellow of the American College of Physicians since 1932

W L SHEEP, M D , F A C P ,
Colonel, Medical Corps, U S A

DR RICHARD BARRETT OLESON

Dr Richard Barrett Oleson (Fellow), of Lombard, Illinois, died on August 6, 1937, at the Johns Hopkins Hospital Death ensued as a result of a septicemia following a prostatic operation

Dr Oleson was born in Bloomington, Ill , in 1870 His preliminary education was obtained in the public schools of Bloomington, Columbus (Ohio), and Lombard He completed his preparation for college at Wheaton College Academy, Wheaton, Ill Later, he attended the University of Wisconsin He received his degree of Doctor of Medicine from the Northwestern Medical School in 1893, and immediately thereafter served an internship of eighteen months' duration at the Cook County Hospital For some years he was Medical Attendant at the Country Home for Convalescent Children, at Prince Crossing He served one year as Clinical Assistant in the Dispensary of the Johns Hopkins Hospital, 1919-20

For many years he practiced Internal Medicine, specializing in Gastroenterology, in Lombard He was widely known throughout his neighborhood, and highly respected as a physician of exceptional ability and character At one time he did postgraduate work at the Trudeau School of Tubercu-

lois, Saranac Lake, N Y He contributed a number of excellent articles to the literature, and was active in medical society work He was a member of the Chicago Medical Society, the Illinois State Medical Society, the American Medical Association and was a Fellow of the American College of Physicians since 1922

Dr Oleson will be sorely missed in the community which has suffered this loss For years he had given superior medical service to the people among whom he lived, and he enjoyed a wide reputation The profession has lost an outstanding man who rendered excellent service to the people whose good fortune it was to have known him

JAMES G CARR, M D , F A C P ,
Governor for Northern Illinois

ERRATUM

“ The Acute and Subacute Pulmonary Involvement in Rheumatic Fever with Notes on the Complication of Basal Pulmonary Collapse ” by Dr Benjamin A. Gouley, pages 626-636, October ANNALS OF INTERNAL MEDICINE. The last four references in the text were not included in the reference list at the end of the article. They are as follows:

- 11 WENCKEBACH, K. Verhandl. d. deutsch. Gesellsch. f. Kreislaufforsch., 1935, viii, 32
- 12 SCHOEN, R. Die Pneumonoze, Verhandl. d. deutsch. Gesellsch. f. Kreislaufforsch., 1935, viii, 94
- 13 PARKER, F., JR., and WEISS, S. Significance of lung changes in mitral stenosis, Am. J. Path., 1936, \ii, 573
- 14 EWART, W. Practical aids in the diagnosis of pericardial effusion in connection with the question of surgical treatment, British Med. J., 1896, i, 717

SMALLPOX VACCINE

gives a high percentage of "takes" in primary vaccinations because:

- 1 An Active Seed Virus is used.
- 2 Calves producing vaccine are kept under sanitary conditions
- 3 Careful technic in the vaccination of animals
- 4 Vaccine is collected with aseptic care.
- 5 Necropsy reports must show animals were in perfect health before the vaccine is distributed.
- 6 Bacteriologic tests are conducted to insure a vaccine free from pathogenic organisms
- 7 Potency and clinical tests are made on each lot of National Smallpox Vaccine insuring an active and satisfactory vaccine

The potency of Smallpox Vaccine is higher and the danger of wound infection is minimized during the cold weather

METABOLISM TESTS

are an Effective Aid
in Medical and
Surgical Practice

For doctors specializing in *internal medicine* as well as those in *general practice*, metabolism tests offer a correct guide for diagnosis and treatment of thyroid diseases, endocrine dysfunctions, heart and blood diseases

For *surgeons*, a series of metabolism tests provides guidance in treatment of *toxic goiter* cases, because the BMR is a factor which determines whether or not immediate operation is advisable. In the past two years, over a thousand doctors have selected Sanborn MODEL E-I-S for metabolism tests in routine practice. This latest Sanborn model fulfills the exacting requirements for a *modern metabolism tester*.

MODEL E-I-S Sanborn Motor-Graphic Metabolism Tester

Sanborn MODEL E-I-S offers

- Accurate Results
- Easy Breathing for Patient
- Simplified Technique
- Convenient Portability
- Complete Equipment with all Accessories
- Low Operating Costs
- Unduplicated Factory to User Price

- **Where did you stay?**
What did you see? Whom did you
meet in New York?

Those are the three questions your friends will ask when you return from New York. In answer to the first question, there are people all over the world who will tell you that New York just isn't New York without staying at The Waldorf-Astoria. In answer to the second question, all visitors include The Waldorf in their itinerary of "things to see," so you will achieve a double satisfaction in staying there! and as for the third question, as The Waldorf is world-famed as the meeting place of celebrity and distinction, what happier answer can you give than to tell of the people you met at The Waldorf-Astoria?

The distinguished address of The Waldorf is also central to all the other things you want to see . . . and the "About-The-City-Bureau" will make all the arrangements for seeing them.

Meanwhile, we welcome you to The Waldorf-Astoria.

ANNALS OF INTERNAL MEDICINE

OFFICIAL PERIODICAL OF THE AMERICAN COLLEGE OF PHYSICIANS

Place of Publication—Prince and Lemon Sts, Lancaster, Pa

Editorial Office—University Hospital,
Baltimore, Md

Executive Office—4200 Pine Street,
Philadelphia, Pa

THE ANNALS OF INTERNAL MEDICINE is published by the American College of Physicians. The contents consist of contributions in the field of internal medicine, editorials, book reviews, and a section devoted to the affairs of the College.

MANUSCRIPTS All correspondence relating to the publication of papers and all books and monographs for review should be addressed to the editor. No manuscripts will be accepted without his consideration. Bibliographic references are to conform to the following style.

4 DOE, J. E. What I know about it, Jr. Am Med Assoc, 1931, xcvi, 2006-2008

Six illustrations per article are allowed without cost to the author. Beyond this number the author must pay the actual cost of illustrations.

REPRINTS For each article published, there will be furnished gratis fifty reprints without covers. An order slip for additional reprints, with a table showing cost, will be sent with galley proof to each contributor. If additional reprints over the first fifty are wanted the order slip must be returned to the printer at the time corrected galley proofs are sent to the Editor.

REVIEWS The ANNALS will make an especial feature of the reviews of monographs and books bearing upon the field of internal medicine. Authors and publishers wishing to submit such material should send it to the editor. While obviously impossible to make extended reviews of all material, an acknowledgment of all books and monographs sent will be made in the department of reviews.

SUBSCRIPTION This periodical is issued monthly, new volumes beginning with the July number each year. Subscriptions may be by the volume or year, but the volume basis is especially recommended. Volumes will consist of approximately 1,400 pages. Subscription price per volume, or per annum, net postpaid \$7.00, United States, Canada, Mexico, Cuba, Canal Zone, Hawaii, Porto Rico, \$7.50, other countries. Prices for back volumes or numbers furnished upon application. Single numbers, current volume, when available, \$1.00. Members of the American College of Physicians receive the ANNALS OF INTERNAL MEDICINE as a part of their membership. Checks should be drawn to the order of W. D. STROUD, M.D., Treasurer, and remitted through the Publication Office or the Executive Secretary's Office.

BUSINESS CORRESPONDENCE. All correspondence relating to business matters, advertising, subscriptions to the ANNALS, inquiries concerning membership in the American College of Physicians, et cetera, should be addressed to the Publication Office or to the Executive Secretary. Books and reprints presented to the College Library should be addressed to the Executive Secretary.

BUFFERED ALKALINIZATION by the safe, physiological process

WHERE buffered alkalization is desirable—as during sulfanilamide administration, in the treatment of colds, influenza and other seasonal respiratory affections—Kalak offers these clinical advantages

(1) It presents a balanced combination of bicarbonates in solution (2) It contains the mineral substances normal to the blood (and no other)

Kalak's high buffering value helps to maintain the urinary pH of 7.4 which has been found so desirable in sulfanilamide therapy

KALAK

is synthetically prepared—is hypertonic, uniform in composition, definite in alkali potency

*He no longer
needs to defend
his use of
Accurate
Scientific
Instruments*

SKEPTICISM of the doctor toward the use of scientific instruments has almost entirely disappeared. Modern medicine uses every sound aid offered by science to arrive at an accurate diagnosis.

In referring to heart disease, Sir Thomas Lewis said "Electrocardiography is essential to the modern study of heart disease is the last court of appeal and its judgment is, practically speaking, infallible."

Since its introduction almost a quarter of a century ago, the "Hindle" Electrocardiograph, one of the earliest truly scientific instruments used in medicine, has been built for and used with confidence by leaders in Cardiology. Basically sound since the beginning, the "Hindle" has been progressively improved, but only after the soundness of each new feature has been proved in practice.

Today's "Hindle," the most modern of Electrocardiographs, has not—from the standpoint of results produced—made obsolete the first "Hindle" (still in regular service). Send for further information.

ELECTROCARDIOGRAPH

Useful in Cardiac conditions

AMINOPHYLLINE is acknowledged as a diuretic and myocardial stimulant. It has likewise been found useful by many cardiologists in the relief of cardiac pain and as an adjunct to digitalis medication.

Aminophylline Squibb (Theophylline with Ethylene Diamine, U S P XI) is the double salt of theophylline and ethylene diamine. The combination is about 25 times more soluble than theophylline alone—a distinct advantage over the older xanthine derivatives.

Aminophylline Squibb is available in tablets of 100 mgm ($1\frac{1}{2}$ grains) and also in crystalline form for prescription use. Tablets Aminophylline Squibb are supplied in bottles of 10 and 100—Aminophylline Squibb in 10-Gm vials and 1-oz bottles.

Announcing for the higher pneumococcus types

ANTIPNEUMOCOCCIC RABBIT SERA (Including Type 3)

THE DEVELOPMENT OF THERAPEUTIC RABBIT SERA for the higher type pneumococcus pneumonias is important news. Now physicians are afforded a specific measure for the treatment of pneumonia types some of which (notably Type 3) frequently terminate fatally and for which routine therapeutic measures only have heretofore been available. Clinical results with some of these serum types have been highly encouraging as far as they have gone and there have even been cures of bacteremic cases in Type 3 and other higher-numbered type infections.

Lederle Laboratories now announce rabbit sera for Type 3, Type 6 and Type 14. Sera for additional types will follow within a few weeks in the expectation that therapeutic sera for all 30 types of pneumococcic pneumonias will become available during the winter.

Sera of effective potency in many of these higher types cannot be produced in horses. Sera for these higher types are produced in rabbits and have been successfully refined and concentrated as much as ten times. This permits dosage of high unitages with reduced danger of serum reactions.

Upon the first suspicion of lobar or bronchial pneumonia the patient's sputum should be examined by the Neufeld Rapid Typing method to identify the type of pneumonia.

A printed list of 2000 laboratories in the United States and Canada to which sputum may be referred by practitioners for typing has been published in directory form by Lederle and may be obtained free on request.

INVESTIGATE

this Revolutionary

ELECTROCARDIOGRAF

In a little over two years, the Sanborn CARDIETTE has revolutionized electrocardiography. This is a statement of fact.

Two years ago, electrocardiographs were owned chiefly by a comparatively few doctors, and by the larger hospitals, usually in metropolitan centers. Since that time, the CARDIETTE has been enthusiastically welcomed by hundreds of doctors as the accurate, easy-to-use, portable, low-cost, *modern* electrocardiograf that the medical world had long awaited.

Acceptance of this new electrocardiograf has come from foremost cardiologists, after thoro tests and in many cases continued personal use of the apparatus. Internists have awarded it a permanent place among their diagnostic facilities. As a result, progressive men in general practice have also added a CARDIETTE to their equipment with complete confidence in its reliability, and its value in diagnosis.

CARDIETTE has made good its promises as the *modern* electrocardiograf.

It is accurate: hundreds of duplicate tests made with CARDIETTE and older type "standard" electrocardiographs show identical results.

It is easy to use: hundreds are operated by doctors, technicians, and others who had no previous training in electrocardiography and who, in less than an hour, learned to make technically perfect heart records with the CARDIETTE.

It is portable: little larger than your handbag, and weighs only 32 pounds complete with all accessories, ready for a test in *any* location.

And, its continued low price has not meant any sacrifice in quality of construction, excellence of heart records, or dependable performance. Rather, the CARDIETTE has been *constantly improved* and is now a greater *value* than ever.

No longer an experiment, past the "early development" stage, the Sanborn CARDIETTE is today an *accepted* electrocardiograf—in accuracy, good performance, and modern, professional appearance.

We invite your inquiries regarding the CARDIETTE, and the liberal 15-day DEMONSTRATION and TEST PLAN, offered without obligation to interested doctors and hospitals. Special December purchase offer now in effect. Simply address Dept. I.

THE PUBLICITY which has been released in connection with the nationwide campaign to eradicate syphilis has served to acquaint the public with the gravity of the disease. Applications for treatment are increasing and thus, with syphilis brought in the open, it is now easier for the medical profession to institute and maintain effective treatment.

Among the antisypilitic products used by physicians, two Squibb preparations—Neoarsphenamine and Iodobismutol with Saligenin—have been found to be most effective.

Neoarsphenamine Squibb is prepared to produce maximum therapeutic benefit. It is subjected to exacting controls to assure a high margin of safety, uniform strength, ready solubility and high spiro-

cheticidal activity. Equally effective when indicated are Arsphenamine Squibb and Sulpharsphenamine Squibb.

Iodobismutol with Saligenin provides all the systemic effects of bismuth in the treatment of syphilis. It presents bismuth largely in an anionic (electro-negative) form. It is rapidly and completely absorbed and slowly excreted, thus providing a relatively prolonged bismuth effect. Repeated injections are well tolerated in both early and late syphilis.

Iodobismutol with Saligenin is a propylene glycol solution containing 6 per cent sodium iodobismuthite, 12 per cent sodium iodide and 4 per cent saligenin (a local anesthetic).

Knox Gelatine (U.S.P.) an Important Vehicle in GASTRIC DISTURBANCE DIETS

When advising a diet for gastric disturbances, remember that Knox Gelatine (U.S.P.) is a valuable vehicle. Knox Gelatine is not only an easily digested protein but blends with whatever foods are allowed into tempting salads and desserts.

In hyperacidity cases or in treating ulcers frequent meals are recommended. Jellied fruit juice or a bland, slightly sweetened gelatine dessert is a variant to the usual between meal beverage.

Knox Gelatine is scientifically made from selected long, hard, shank beef-bones — surpasses minimum U.S.P. requirements — pH about 6.0 — contains no carbohydrates — fat content less than 0.1% — odorless — tasteless — bacteriologically safe.

*In daily menus and prescribed diets
use Knox Gelatine*

Recipe

Dessert with strained prune pulp

PRUNE WHIP (six servings)

- 1 Soak Gelatine in cold water about 5 minutes, using
 - 1 envelope Knox Sparkling Gelatine
 - $\frac{1}{4}$ cup cold water
- 2 Add to the following, stirring thoroughly
 - $\frac{3}{4}$ cup hot prune juice
 - 1 cup cooked prune pulp
 - 2 tablespoonfuls lemon juice
 - $\frac{1}{2}$ cup sugar
 - $\frac{1}{4}$ teaspoonful salt
- 3 Cool. When mixture begins to thicken, fold in
 - 2 egg whites, stiffly beaten
- 4 Rinse mold or dish in cold water, and fill with dessert. Chill. To serve, unmold and garnish with whipped cream, or serve with custard sauce.

Prescribe **MALTINE WITH COD LIVER OIL** *for enhanced vitamin efficacy*

For 62 years MALTINE WITH COD LIVER OIL has had the respect and support of physicians. Today it is still one of the most convenient and efficient means of prescribing vitamins A and D. Biological experiments have proved that the efficacy of the vitamin A content of cod liver oil is enhanced twofold by emulsification with Maltine. Besides the vitamin content and other factors of cod liver oil, MALTINE WITH COD LIVER OIL affords the valuable constituents of Maltine itself. Another advantage of MALTINE WITH COD LIVER OIL is the absence of the usual unpleasant oily consistency of vitamin-bearing oils.

When iron iodide is indicated, MALTINE WITH COD LIVER OIL and IRON IODIDE is suggested. This product contains two grains of freshly prepared iron iodide per fluid ounce. The Maltine Company, 60 Hudson Street, New York City.

PLASMA COLLOID OSMOTIC PRESSURE AS A FACTOR IN EDEMA FORMATION AND EDEMA ABSORPTION *

By ARTHUR C. KERKHOFF, B S., Ph D., M D., *Minneapolis, Minnesota*

THE proteins of the blood plasma being hydrophilic colloids in solution must exert an osmotic pressure. This osmotic pressure measures the momentum of the impacts made by the colloid particles on a unit of surface. Water and salt will pass from the outside to the inside of a tube whose wall is permeable to salt and water but is not permeable to colloid particles if there is a salt solution within the tube containing a hydrophilic colloid dispersed in it. Water and salt entering the tube increase the hydrostatic pressure of the fluid within it until this hydrostatic pressure exactly equals the colloid osmotic pressure. Water and salt will be filtered out of such a tube if the hydrostatic pressure within the tube is higher than the colloid osmotic pressure. This process is known as ultrafiltration and the filtration of water and salt proceeds until the concentration of the colloid within the tube is such as to determine a colloid osmotic pressure equal to the hydrostatic pressure.

The walls of the capillaries are ultrafilters. They allow salts and water to filter through them in both directions but in their normal state they tend to prevent the filtration of the plasma proteins across their walls. The permeability of an ultrafilter membrane can be changed so that it will allow not only water and salts through it but also colloid particles of various sizes. Under these circumstances it is a "leaky" ultrafilter membrane and the fluid on both sides of the membrane will contain colloid. The first problem is to determine whether edema fluid is a pure ultrafiltrate containing salts and water in the same proportions as in the blood plasma but with very little or none of the proteins of the plasma. In order to determine this we have examined specimens of edema fluid (anasarca) from eight cases of nephritis and have found the total plasma proteins in this fluid to vary from 0.04

* Received for publication March 29, 1937.

From the Department of Medicine of the University of Minnesota at the Minneapolis General Hospital.

per cent to 0.25 per cent (table 1) The mean value is 0.13 per cent We have also examined the ascites of a dog made edematous within a period of

| E | 29% | 335 | 393 | 337 | 366 | Congestive heart failure due to mitral disease |
| H W | 1% | | | | | Congestive heart failure Mitral stenosis |

These somewhat higher values in heart failure are probably explained by the fact that the increased capillary pressure which increases the tendency to filtration in heart failure is accompanied by a dilatation of the capillaries and stasis Landis¹ has shown that stasis and dilatation can bring about some leakage of protein through a normal capillary ultrafilter There is

also frequently a tendency to anoxemia in heart failure. Essex and Ort² have shown that anoxemia alters the permeability of the capillaries. Our values for edema fluid are in essential agreement with the protein concentrations in anasarca fluid found by Darrow, Hopper and Cary,³ Leiter,⁴ Shelburne and Egloff,⁵ and Landis.¹ Beckmann⁶ on the other hand has found higher concentration of protein in anasarca fluid but even the highest figures are less than many of the values found for lymph from a dog's leg by Drinker and Field^{7, 8} and by Weech, Goettsch and Reeves.⁹ We were very careful to avoid contamination with blood in collecting our specimens. The edema fluid was allowed to flow freely from the Southey tubes inserted into the subcutaneous tissues for at least a half hour before collecting in test tubes for chemical examination. It is reasonable to assume from our figures that the capillary is a fairly good ultrafilter during the process of formation of edema in nephritis but is probably a little more "leaky" in heart failure.

THE MECHANISM OF EDEMA FORMATION

Starling¹⁰ paved the way to an understanding of the mechanism of edema formation when he performed his perfusion experiments on dogs. His experiments proved definitely that the presence of colloid within the perfusion fluid decreased the tendency to edema. Edema occurred when only salts and water were used as perfusion liquid. Before the abnormal conditions may be discussed, it is necessary that one analyze the normal mechanism of fluid exchange in the tissues. We know from the work of Landis¹¹ that there is a gradual pressure fall along the capillary. Normally the average pressure at the arterial end of the capillary is 32 mm Hg. At the venous end of the capillary, the pressure is about 12 mm Hg and at the middle of the capillary loop about 22 mm Hg. This, of course, is exactly what was predicted by Starling and Schade¹² in their early discussions of the subject, but until the work of Landis actual values for these pressures were unknown. This capillary pressure tends to force water and salt through the capillary wall and out into the tissue spaces. The colloidal osmotic pressure opposes this tendency for water and salt to leave the capillaries. From values we shall present later, it will be seen that the average colloidal osmotic pressure in man is 22 mm Hg and therefore exactly equals the hydrostatic pressure within the capillary at the middle of the loop. It is therefore quite obvious that at the arterial end of the capillary, water and salt will be forced out of the vessel into the tissue spaces as long as the hydrostatic pressure is greater than the osmotic pressure. When these two pressures become equal, as they do in the middle of the capillary, fluid and salt will enter into the vessel as fast as they leave and no loss or gain will occur. At the venous end of the capillary, however, the osmotic pressure is higher than the hydrostatic pressure and therefore water and salts will stream into this half of the tube. Therefore in a normal capillary the amount of fluid

and salt forced out of the capillary at its arterial end will be approximately equalled by the amount of water and salt "pulled" into this tube at the venous end. We have modified Schade's original diagrams of fluid exchange in the capillary. Figure 1 represents the normal mechanism of fluid exchange along the capillary.

Normal mechanism

FIG 1 Graphic presentation of fluid exchange in the capillaries

Hydrostatic pressure and colloid osmotic pressure are not the only factors involved in edema formation. From this very simple discussion of normal fluid exchange in the capillaries, it appears obvious that the following factors might cause increased transudation and lead to edema formation: (1) increased hydrostatic or capillary pressure, (2) decreased plasma colloid osmotic pressure, (3) increased permeability of the capillaries, and (4) increased colloid osmotic pressure in the tissue surrounding the capillaries. Of these factors we believe that the increased hydrostatic pressure and the decreased osmotic pressure within the capillary are the most important. The hydrostatic pressure of edema fluid within the tissues themselves can not be wholly disregarded. In one case of edema due to heart failure we found this hydrostatic pressure to be approximately 8 cm of water. This would decrease the active filtration pressure by just that much and thereby decrease the tendency to formation of further edema.

Let us now see what will happen if we vary some of the forces normally active in fluid exchange. If, for instance, we should increase the venous pressure, the point of balance between hydrostatic pressure within the capillary and osmotic pressure of the plasma colloids will shift towards the venous end of the capillaries (Figure 2). This will allow more fluid to pass out of the capillary since a greater proportion of the capillary will have a hydro-

static pressure higher than the osmotic pressure. If this process continues for any length of time it is obvious that edema must result. This is what happens when the right heart fails and the venous and capillary pressures rise in consequence of this heart failure. If instead of increasing the venous pressure we should decrease the colloid osmotic pressure (figure 3) and the

Mechanism with increased venous pressure (congestive heart failure)

FIG 2 Graphic presentation of fluid exchange in the capillaries

Mechanism with reduced colloid osmotic pressure

FIG 3 Graphic presentation of fluid exchange in the capillaries

capillary pressure remains the same, the equilibrium point will again shift to the venous end of the capillary and more of the capillary will be given over to transudation and less to absorption. This also would lead to edema formation. In our opinion this is exactly what happens in nephrosis and nephritis with edema. At this point it might be well to consider that the body might accommodate itself to this lowered colloid osmotic pressure by reducing capillary pressure. If such should occur, a state might be reached much as is diagrammatically represented in figure 4. It is possible that this

Possible compensatory vascular mechanism with reduced colloid osmotic pressure

FIG 4 Graphic presentation of fluid exchange in the capillaries

mechanism is at times called upon for we shall see that certain reductions in colloid osmotic pressures can occur without edema. Below a certain value edema will practically always result because the body can not accommodate itself to these very low colloid osmotic pressures.

Up to the present we have not taken into consideration the possibility that there could be an increased permeability of the capillaries. In our discussion of the capillary wall as an ultrafilter we have stated that very little protein leaks through, so that if the capillary has become more permeable, it apparently has become more permeable only to salts and water. Such a permeability would not alter the mechanism of edema formation unless a change in permeability would occur only in one end of the capillary and not the other. If we assume, and it appears logical to do so, that the changes in permeability must of necessity occur throughout the whole capillary, then any such change would make no difference in the amount of edema. It

* In acute and chronic nephritis heart failure is often present also and the increased capillary pressure is an added factor in edema formation.

is obvious that if more fluid is forced out of the capillary in the arteriolar end, more fluid will also be re-absorbed into the capillary at the venous end, so that although more fluid may pass through the capillary wall in both ways, the end result is the same

If the capillary wall loses its property of holding back colloid particles then there will be a colloid osmotic pressure developed by the protein particles in the filtrate on the outside of this "leaky" capillary. This colloid osmotic pressure of the proteins in the filtrate surrounding the "leaky" capillary will tend to increase the filtration rate across the wall at the arterial end of the capillary and to decrease the absorption of fluid at the venous end. In other words the "leaky" ultrafilter tends to reduce the effectiveness of the osmotic pressure of the proteins within the capillary by exactly the amount of colloid osmotic pressure present in the ultrafiltrate on the outside. Calculations of the actual colloid osmotic pressure of concentrations of serum proteins of the order of those found in edema fluids show them to be negligible as factors in edema formation

THE MEASUREMENT OF COLLOID OSMOTIC PRESSURE

Starling¹⁰ was the first to measure the osmotic pressure of the plasma colloids. He obtained a value of 30 to 41 mm Hg for the normal osmotic pressure of the plasma colloids. From values of the capillary pressure given by Landis,¹¹ we know that these original measurements were far too high. This can be accounted for by his method which was to take concentrated serum, determine the colloid osmotic pressure and calculate the normal osmotic pressure on the basis of a straight line relationship between concentration and pressure, thereby disregarding the very large relative volume of the colloid particles or the "b" factor of the Van der Waals equation for the relation between pressure and volume of a gas. Other errors also crept into his method, such as inconstancy of temperature and the long time necessary for completion of the experiment which allowed changes to occur in the protein micel. Later Verney¹³ in Starling's laboratory used a modification of the Starling method and obtained values from 22.8 to 25 mm Hg. Krogh¹⁴ in 1929 obtained a value of 27.9 mm Hg. Govaerts¹⁵ in 1924 found pressures of 25.7 to 29.4 mm Hg in the normal and in cases of nephritis with edema 8.8 to 9.6 mm Hg. Landis¹⁶ in 1930 using a method similar to Starling's obtained a value of 18.3 mm Hg for normal osmotic pressure. Kylin¹⁷ in 1929 obtained a value of 30 mm Hg and Muntwyler, Way, Binns and Myers¹⁸ in 1933 found the normal osmotic pressure to be from 21.7 to 25.2 mm Hg. After Sørensen¹⁹ had laid the foundation for the dynamic determination of the colloid osmotic pressure, Schade¹² saw the advantages in this method and perfected a microtechnic. We have used the Schade method in all our determinations. This does away with all the disadvantages of the Starling method in that the temperature is kept constant so that the osmometer will not act as a thermometer. The plasma is used

in its normal concentration and the entire experiment requires only 2 to 4 hours. We have been able to demonstrate with our method that the above mentioned factors can cause great differences in the pressure readings. For example, using our method a sudden change in temperature of 0.1 of a degree C can give errors of the order of 25 per cent. We have also determined that allowing sterile plasma to stand at room temperature for 48 hours may increase the osmotic pressure as much as 19 per cent. Since in this method we are actually performing ultrafiltration and not measuring the osmotic pressure of the plasma against water or any other solution, there will be no difference in ionic concentration on the two sides of the membrane other than that brought about in accordance with the Donnan equilibrium. We are therefore actually measuring the colloid osmotic pressure as it affects ultrafiltration in the human capillaries or in other words the "effective" colloid osmotic pressure.

NORMAL COLLOID OSMOTIC PRESSURE OF THE BLOOD PLASMA IN MAN

We²⁰ have examined colloid osmotic pressure in 22 normal persons and have found the mean pressure to be 21.4 mm Hg at 37° C (table 3). The experimental error of our procedure showed a standard deviation of the

TABLE III

mean of 0.6 mm Hg or a probable error of the mean of 0.4 mm Hg. The biological scatter is measured by a standard deviation of ± 2.5 mm Hg. The values ranged from the lowest value of 17 mm Hg to the highest value of 25.3 mm Hg. Our mean agrees very well with the mean value for pressure in the middle of the human capillary as determined by Landis' measurements. Values very much higher than these would lead to an absorption of the body fluids into the blood vascular system, their excretion through the kidneys, and a consequent dehydration of the body. Values much lower than these would lead to generalized edema formation. We believe that our mean is very close to the actual value. Our values are in essential agreement with those obtained by Schade,¹² Verney,¹⁸ Landis,¹⁶ and Muntwyler, Way, Binns and Myers¹⁸ and are much lower than those obtained by Stirling,¹⁰ Krogh,¹⁴ Govaerts¹⁵ and Kylin.¹⁷

We have determined the colloid osmotic pressure of normal dogs and have found it to average 18.5 mm Hg. The highest value was 21.7 and the lowest value 17.2 mm Hg (table 4).

TABLE IV
Colloid Osmotic Pressure Values in Normal Dogs

| Date | Albumin | Globulin | Fibrinogen | Total Protein | Osmotic Pressure mm Hg at 37° C |

Mean pressure 18.5 mm Hg

(These values are not corrected for the error due to the addition of sodium oxalate as the anti-coagulant.)

COLLOID OSMOTIC PRESSURE OF THE BLOOD PLASMA IN CASES OF NEPHROSIS AND NEPHRITIS

We²¹ have made 24 determinations of the colloid osmotic pressure in 14 cases of nephritis with edema (table 5). Whenever edema was present, the colloid osmotic pressure was always lower than 15 mm Hg, when the colloid osmotic pressure was 16 mm Hg or more, edema was absent or was being absorbed. The average colloid osmotic pressure for these edematous cases was 8 mm Hg. This value agrees well with the values obtained by Govaerts,¹⁵ Schade,¹² Fahr and Swanson,²² Muntwyler, Way, Binns and Myers¹⁸ and Kylin.¹⁷ The colloid osmotic pressure of one case of chronic nephritis in uremia without edema was found to be 27 mm Hg. This patient, however, had hypertension and we have found that in hypertension

the osmotic pressure of the plasma proteins tends to be slightly higher than normal

THE EFFECT OF GUM ACACIA INJECTIONS ON NEPHROTIC EDEMA IN MAN

In order to demonstrate that the edema in nephrosis and nephritis was due merely to a reduced colloidal osmotic pressure in the plasma, we searched for some inert colloid which could be injected into the blood stream and which would have no other effect than to raise the colloid osmotic pressure. Hartmann²³ had shown that the intravenous injection of 30 per cent gum acacia in nephrotic patients led to a diuresis. Thirty per cent gum acacia solution has a colloid osmotic pressure many times higher than that of normal plasma. In fact, a 6 per cent gum acacia solution has approximately the same colloid osmotic pressure as normal plasma. Therefore it should be possible by injecting sufficient amounts of 30 per cent gum acacia to raise the colloid osmotic pressure to a point where edema would be absorbed. Referring back to our scheme of a capillary if we raise the colloid osmotic pressure sufficiently we should move the equilibrium point near the middle of the capillary and therefore have less transudation and more absorption. We have injected this solution into six patients with nephritis or nephrosis. In only three of these cases was it possible to inject enough gum acacia to produce the desired effect. However, when sufficient gum acacia could be

TABLE VI
The Effect of the Injection of Gum Acacia in a Case of Subacute Glomerulonephritis with Edema

injected without severe reactions marked diuresis followed. We shall give the results of only one of these experiments performed in a case of subacute glomerulonephritis with very marked edema (table 6). The colloid osmotic pressure was 8 mm Hg and the patient on an intake of 400 c c a day was barely maintaining her fluid balance. She was neither gaining nor losing edema. On the first day of the experiment she was given intravenously 300 c c of 30 per cent salt-free gum acacia furnished by the Eli Lilly Co. This day with an intake of 600 c c her output rose to 1900 c c, a loss of approximately 1300 c c of body fluid. The next day she was given 400 c c of gum acacia and again lost approximately 1300 c c of fluid. The third day she was given 300 c c gum acacia and lost approximately 1400 c c more fluid than she took in. On this third day the osmotic pressure of the plasma colloids was 12 mm Hg before the last injection of gum acacia, while after the injection the osmotic pressure was 15 mm Hg*. Several days later the osmotic pressure was still 13 mm Hg. The patient continued to put out large amounts of fluid. In a period of seven days she lost 11 liters of edema fluid with a corresponding loss in weight. The mere addition of an indifferent colloid to the blood plasma increased the total colloid osmotic pressure to a point at which fluid was drawn into the blood, carried to the kidneys and excreted as urine, thus producing a marked diuresis. During the time of this very marked diuresis of water there was also a very marked increase in the output of salt. At the height of the diuresis, the patient put out 17.4 gm of salt in one day on an intake of 2.5 gm of salt. In other words, this patient was putting out urine which contained nearly the same amount of salt as is present in normal tissue fluid. This tends to prove that the kidney is able to excrete salt very readily in nephrosis or nephritis with edema if the colloid osmotic pressure is raised sufficiently so that tissue fluid can be absorbed. These experiments also prove that the increase of the colloid osmotic pressure by some inert colloid not normally found in the blood is sufficient to cause an absorption of the edema with consequent excretion of water. The kidney itself has no difficulty in excreting water and salt if water and salt can be absorbed from the tissue spaces.

CONCLUSIONS

1 The edema fluid in nephritis, nephrosis and cardiac failure is a nearly pure ultrafiltrate of the blood plasma.

2 The formation of edema is for the most part a result of imbalance between the forces of capillary hydrostatic pressure and colloid osmotic pressure of the plasma. A substantial increase in capillary pressure or decrease in colloid osmotic pressure or a combination of both results in edema formation.

3 The method of Schade for the determination of the "onkotic" pres-

* Immediately after injecting gum acacia fluid is drawn into the blood, the plasma volume is increased and the colloids are diluted. Therefore the calculated colloid osmotic pressure is never attained.

sure is the logical method for the determination of the "effective" colloid osmotic pressure of the plasma because it measures the hydrostatic pressure at which ultrafiltration of the plasma salt and water just equals the reabsorption. For this reason in using this method it is unnecessary to calculate or measure the Donnan effect. The thermostatic control of temperature rules out any sudden thermometric effect during the measurement.

4 The normal colloid osmotic pressure of the plasma in man is approximately 21.4 ± 2.5 mm Hg.

5 The normal colloid osmotic pressure of the plasma in dogs is 18.5 mm Hg.

6 In nephrosis and nephritis with edema the colloid osmotic pressure is usually lower than 15 mm Hg and averages 8 mm Hg.

7 The injection of concentrated solutions of an inert colloid (gum acacia) increases the colloid osmotic pressure of the plasma and causes a disappearance of the edema with a corresponding diuresis of water and salt in the same proportions as they are found in edema fluid.

8 Retention of salt in nephritis is not due to renal insufficiency but is consequent to prerenal deviation in the ultrafiltrate or edema fluid.

CUTANEOUS MANIFESTATIONS IN PSYCHOTIC AND PSYCHONEUROTIC INDIVIDUALS *

By EUGENE F BOGEN, M D , *St Cloud, Minnesota*

IT is known that, as a result of their disorder, a small percentage of individuals with nervous or mental abnormalities develop habits which result in skin lesions, or even may become victims of constantly self-inflicted injuries to the skin or mucous membranes. These are cases of true dermatitis factitia. Some of these acts may be the result of a desire for attracting sympathy or attention to the individual, as in one of the cases mentioned recently by Klauder ¹ in which a hysterical woman systematically and secretly used lysol to produce extensive wheals or bands on her arms, which were exhibited to her acquaintances for their commiseration. Such cases are, however, merely behavior problems, although a mental or nervous disorder is responsible for the abnormal habit, it is not directly causative of the cutaneous lesion.

There appears to be a certain amount of evidence that in various psychoses, psychoneuroses and neuroses, in some types more than in others, there is a tendency to the development of more or less definite types of skin diseases, that is to say that, whatever may be the mode in which the effect is produced, these mental and nervous disorders are etiologic factors in the production of certain types of skin lesions.

The literature dealing with this subject is not voluminous, and, especially as regards the psychoses and psychoneuroses, is indefinite and lacking in clinical precision. I have, therefore, thought that it would be of interest to set down my personal clinical findings in the observation of a very considerable number of psychotic and psychoneurotic patients, in a definite percentage of whom skin lesions were observed, without there being, so far as could be observed, any other etiologic factor than the psychogenic one, further, to classify as far as possible the types of cutaneous lesions associated with definite psychogenic states and finally, to give the therapeutic result following a particular mode of treatment.

The data, which I have tried to make as complete as possible in regard to the clinical aspects, may, I hope, induce others, who have the opportunity, to make similar observations, with a view of verifying whether it is merely a conjecture or an established fact that psychogenic disorders are definite etiologic factors in cutaneous disorders, also, perhaps, to discover the mode of causation.

Theoretically, there are different ways in which nervous and mental disorders may affect the skin, especially its trophism. Of these perhaps

* Received for publication April 10, 1937

Permission granted by Chas M Griffith, Medical Director, U S Veterans Administration, Washington, D C

the most likely are the increased excitability and emotionality, acting probably on either or both the endocrine or other body secretions or the autonomic nervous system, particularly the trophic or sensory nerves supplying the nutrient vessels. Such factors are known to affect the skin in normal as well as in neurotic and psychotic subjects, but in psychotics especially the abnormal emotionality should be a particularly strong factor in producing effects upon the skin, although we are much in the dark in regard to the exact mechanism of such production.

A brief resume of the available literature will be in order before my personal contribution. It will be noted that the authors ^{giving} more attention to the effects of emotionality upon the skin in ^{red} give subjects than in psychotics or psychoneurotics.

Eller² was one of the first in this country, in 1929, to write on the subject of nervous and mental factors affecting the skin. He mentions as a recognized fact that the blood vessel tonus is regulated by several factors, among which may be included the psyche acting through the visceral nervous system, either the parasympathetic or sympathetic. These in turn may be influenced by the internal secretions. This vascular influence, of course, occurs in the skin as well as in other organs.

According to Eller, the skin conditions occurring in this group are (1) dermatitis factitia, (2) the compulsion neuroses, namely, dermato-thalassia, etc., (3) dermato-phobias, (4) emotional urticaria, (5) hysterical pemphigus, which is said to exist, (6) alopecia areata, lichen planus and certain eczemas of psychogenic origin.

Eller cited Strandberg who observed the frequent occurrence of vasomotor and trophic disturbances of the skin in insane persons, among which he included acrocyanosis, abnormal hair growth, anomalies of sweat secretion, trophic and other disturbances of the nails, etc., especially in patients with dementia praecox.

Bonjour,³ writing in 1929 upon the influence of the mind on the skin, cites Sack (of Baden-Baden) who expressed the belief that in certain psychogenetic phenomena the skin could be used as an organ of expression, especially if it had some pathologic disposition to act thus. Bonjour himself thought that warts, eczema and urticaria could be therapeutically influenced by suggestion, patients showing such lesions were persons whose nervous systems were affected either through emotions or through some other cause of excitement.

Joltrain⁴ states that "Emotional shock is always followed by a humoral disequilibrium—a hemoclastic crisis which is always followed by a series of phenomena. Herpes, dermatographism, etc. appear after strong emotions in those having such a disposition. Emotion can be considered as an antigen, as something which in a hypersensitive organism frees sensitizing substances."

Horan⁵ insists that the emotions acting through the endocrines and cir-

culatory systems can and do bring about many pathologic conditions of the skin

Stokes ⁶ of Philadelphia, writing in 1932, says "I have reached the belief that it is often impossible really to comprehend the urticarias of adult life, which are of more than two weeks' duration, without a genuine study of the personality problems involved" In an article published in 1930 Stokes and Pillsbury ⁷ stated "The larger our experience, the more careful our search, the more we are inclined to believe that in the urticarias and urticarial dermatitides of middle life, in the diathetic eczemas and rosacea, and even in dermatoses, which, like epidermatophytoses, seem far removed from psychologic considerations, the tension make-up, the personality defect, the conflict and anxiety, the repression and complex, have their place as causal influences" These writers considered that the mode in which the psychologic factor acts to produce urticaria was that emotion predisposed to acidity, acidity favored production of the gas bacillus, and the gas bacillus caused production of histamine and wheals on the skin

Crutchfield, ⁸ writing in 1932 upon the emotional and psychic factors in skin disease, classes these types of skin lesions in four groups

- 1 Those in which there is some definite organic pathologic lesion in the sensory or trophic nerve,

- 2 Those conditions which are a result of pathologic changes in the peripheral nerves (trophic ulcers, gangrene),

- 3 Those conditions in which no known pathologic lesions exist in the nervous system but in which skin lesions are pronounced

- 4 Disturbances in the autonomic nervous system This is the group in which emotions play the most important part

There is a less definite class composed of skin diseases which cannot be placed in any anatomic group but which are produced by the emotions of the patient These may be aggravated, prolonged or become incurable due entirely to the mental reactions of the patients

Klauder ¹ has just published an article on the psychogenic aspects of skin diseases He gives a long list of such lesions which, besides those of a circulatory or sensory nerve origin, includes stigmata, trichotillomania, angiospasm, etc He mentions anesthetic areas observed in hysterical patients, also, that psychoneurotics have a peculiar lability of the vasomotor apparatus manifested in disorders of the peripheral circulation Peripheral circulatory disturbances in psychopathy are stressed Klauder thinks that dermatographism of psychoneurotics is closely related with angioneurotic edema, urticaria and frank dermatitis or acute eczema Further, that cutaneous phenomena, characterized by vascular dilatation, erythema and exudation, when appearing and disappearing suddenly are suggestive of psychic or allergic causation

My personal observations refer to skin lesions noted in psychotic and psychoneurotic individuals for which no other etiologic factors could be

found apart from the nervous or mental disturbance. A total of 1350 such patients was observed. The average age was 44 years, the minimum, 38 years. Of this total group, 150 patients were classed as psychoneurotics, and of these 27 (18 per cent) showed or developed skin lesions during the period of treatment, 1200 patients were classed as psychotics and, in these, 76 cases (6.33 per cent) of skin diseases were observed or developed during the period of treatment.

TABLE I
Percentage of Skin Diseases in Sub-Groups of Psychoneuroses
150 Cases (11% of total patients observed)

| Sub-group | No Cases Skin Lesion Observed | Percentage of Psychoneurosis Group |
|---------------|-------------------------------------|--|
| Hysterical | 14 | 9 $\frac{1}{3}$ % |
| Anxiety state | 9 | 6% |
| Psychasthenia | 4 | 2 $\frac{3}{5}$ % |
| TOTAL | 27 | 18% |

Table 1 gives the percentage of each psychopathologic sub-group for the psychoneurotic cases and the total percentage of skin lesion cases observed in each sub-group.

TABLE II
Types of Skin Diseases Accompanying Psychoneuroses

| TYPE | SUB-TYPE | No of patients in group | TYPE OF SKIN DISEASES | No. in group under treatment | Recovered | Improved | Unchanged | REMARKS |
|----------------|---------------------|----------------------------|--------------------------------|---------------------------------|-----------|----------|-----------|--|
| PSYCHONEUROSIS | HYSTERICAL TYPE | 14 | Acne vulgaris | 8 | 2* | 1 | 5 | *Skin lesions cleared up and remained symptom free for over nine months *Suffered a relapse whenever treatment was discontinued *Improved also in general health—mentally and physically |
| | | | Herpes zoster | 4 | 0 | 3* | 1 | |
| | | | Seborrheic dermatitis | 2 | 0 | 1* | 1 | |
| | ANXIETY STATE | 9 | Acne vulgaris | 5 | 2 | 1 | 2 | This entire group improved in general health |
| | | | Eczemas of undetermined origin | 3 | 0 | 1 | 2 | |
| | | | Dermatitis factitia | 1 | 0 | 1 | 0 | |
| | PSYCHIAS- THENIA | 4 | Impetigo | 2 | 0 | 1 | 1 | *Skin lesions cleared up after 2 $\frac{1}{2}$ months of treatment |
| | | | Seborrheic dermatitis | 1 | 0 | 1 | 0 | |
| | | | Urticaria | 1 | 1* | 0 | 0 | |

"Recovered" as here used indicates that the manifestation did not recur for a period of three months.

Table 2 gives the types of skin lesions observed in the foregoing psychoneurotic sub-groups with the result of treatment.

PSYCHOTIC AND PSYCHONEUROTIC INDIVIDUALS

TABLE III

Percentage of Skin Disease in Sub-Groups of Psychoses

PSYCHOSIS

1200 Cases or 89% of Total Patients Observed

| Sub-group | No Cases Skin Lesion Observed | Perce Psy C |
|-------------------------------------|-------------------------------------|-------------------|

TABLE V

Comparative Response to Treatment of Skin Diseases in Psychoneurotic and Psychotic Cases
Total Number of Cases Observed = 1350

| | | |
|--|--|--------------------------------|
| PSYCHONEUROSIS 150 Cases = 11% of Total | Cases in which skin lesions developed 27 Cases or 18% of Group | Recovered = Five or 18% |
| | | Improved = Ten or 37% |
| | | Unchanged = Twelve or 44% |
| PSYCHOSIS 1200 Cases = 89% of Total | Cases in which skin lesions were not observed 123 Cases or 82% of Group | |
| | | |
| | | |
| PSYCHONEUROSIS 150 Cases = 11% of Total | Cases in which skin lesions developed 76 Cases or 61% of Group | Recovered = Nine or 11½% |
| | | Improved = Thirty-two or 42% |
| | | Unchanged = Thirty-five or 46% |
| PSYCHOSIS 1200 Cases = 89% of Total | Cases in which skin lesions were not observed 1124 Cases or 93½% of Group | |
| | | |
| | | |

The skin lesions which were observed in the two groups were as follows

Acne vulgaris
Dermatitis factitia
Pellagra with characteristic facies, pigmentation and exfoliation
Parapsoriasis lichenoides
Psoriasis with deeply infiltrated patches
Ichthyosis hystrix
Herpes zoster
Dermatophobias
Seborrheic dermatitis
Pruritus
Eczemas of undetermined origin

Studies of urine, blood, and basal metabolic rate were made routinely. The urine showed no significant departure from normal. Blood cholesterol was within normal limits in most of the patients. The fasting blood sugar was normal. The basal metabolic rate varied between minus 24 and plus 20. In this group of cases the schizophrenics had the lowest basal metabolic rate. None of these patients, regardless of the metabolic rate, showed any signs of disturbed thyroid function.

Roentgen-rays of the pituitary region showed normal size of the sella turcica without erosion in practically all the cases so studied. One case showed an abnormally large sella but without evidence of erosion.

Treatment of these psychotic and psychoneurotic patients with skin lesions consisted of the administration of U S P standardized thyroid in tablets, in doses from $\frac{1}{4}$ to 3 grains per day, and of injections of $\frac{1}{2}$ c c of antuitrin every other day. The dosages were varied to some extent according to the level of the basal metabolic rate, the pulse, weight, skin lesions and the degree of mental disturbances.

The response to this treatment was more favorable in psychoneurotic than in the psychotic group (table 5). In cases in which improvement took place the change was noted after three or four months of treatment (tables 2 to 4).

The use of this form of therapy was largely empirical. It was suggested by the frequency of endocrine disturbances associated with psychosis or psychoneurosis. The results obtained are not considered decisive.

AN ANALYSIS OF 62 CASES OF PRIMARY CARCINOMA OF THE LIVER BASED ON 24,400 NECROPSIES AT BELLEVUE HOSPITAL *

By EINAR G. GUSTAFSON, M D, *New York, N Y*

THE material for this study of primary carcinoma of the liver was derived from 24,400 consecutive autopsies performed at Bellevue Hospital from 1906 to 1936. In selecting these 62 cases a review of all cases included in our protocols as primary carcinomata of the liver was carried out. Those cases which, either on analysis of the protocols, or, microscopically, did not represent typical examples of carcinoma, were excluded, together with those in which clinical records or microscopic preparations were not available. All cases were likewise excluded in which duct cell carcinoma of the pancreas was suspected, microscopically or otherwise.

In this presentation the classification and diagnostic criteria laid down by Egge¹ are adhered to. Those cases with invasion or destruction, or with metastases, or with neoplastic thrombus formation, visible either grossly or microscopically, or both, are termed carcinoma.

Macroscopically three groups are considered

- 1 The nodular form, in which the neoplastic growth is represented by discrete nodules, varying in size from a few millimeters to several centimeters. These nodules may involve one or more lobes.
- 2 The massive form, in which there is one massive nodule occupying an entire lobe, usually the right. There may be numerous smaller tumor nodules in adjacent liver tissue. This form frequently merges with that of group 1.
- 3 A diffuse form in which it is impracticable to differentiate carcinoma from cirrhosis of the liver, except microscopically.

Microscopically, the differentiation between the primary liver cell and bile duct types is considered. Cases occur in which a differential diagnosis is difficult or impossible to make because of varying pictures in different parts of the tumor growth. These are included under a separate heading, namely, indeterminate or dual origin. According to this microscopic classification, 39 of the Bellevue Hospital cases are of liver cell type, 21 of bile duct type, and 2 of indeterminate or dual origin. These figures are presented at this point in anticipation of further analysis which depends on this division.

No individual survey has heretofore been made of so large a group. Hale-White² analyzed 25 cases occurring in 18,500 necropsies, an incidence of 0.13 per cent. McIndoe and Counseller³ analyzed 62 cases collected from 42,276 necropsies, an incidence of 0.14 per cent. The limits of varia-

* Received for publication June 10, 1937.

From the Department of Pathology, Bellevue Hospital.

tion of incidence extend from 0.08 per cent by McIndoe and Counsellor in their own cases, to 0.33 per cent by Von Glahn and Lamb⁴ and Fried⁵. In the present analysis the incidence was found to be 0.25 per cent, or one case of primary carcinoma of the liver in every 394 necropsies.

The sex incidence in the 62 cases at Bellevue Hospital was 53 males and 9 females. However, accurate figures on the number of necropsies in males and females were not obtainable, the approximate ratio being three males to one female, thus giving a corrected incidence of 18 males to 9 females. Eight of the nine cases in females were in the bile-duct group and one in the liver cell group. The significance of this is not clear. Are the possible underlying etiological factors of significance? Does the predominance of cirrhosis of the liver in males play a rôle? No definite answer to these questions is available as yet.

In the Bellevue Hospital series 53 cases occurred in the white race, 4 in negroes, and 5 in the yellow race (4 Chinese and 1 Japanese). These latter figures comprise 6.4 per cent and 8.1 per cent, respectively, of the present series.

The incidence in negroes parallels the admission rate of that race to Bellevue Hospital. That of the yellow race, however, is much higher than the admission rate. Strong and Pitts⁶ of Vancouver, where the Chinese populace is relatively larger than that of New York City, reported a higher incidence of primary carcinoma of the liver in the yellow race. They reported nine cases of primary carcinoma of the liver occurring in 1024 necropsies. Of the 9 cases eight were in Chinese. The number of necropsies on Chinese in their series was 115, making an incidence of 6.9 per cent in Chinese as compared with 1 case in 909 necropsies in white people, or an incidence of 0.11 per cent.

The yearly percentage incidence in the autopsy series of primary carcinoma of the liver including both liver cell and bile duct origin has shown great variation over the course of years from which this series is taken. No definite trend towards an increasing or decreasing incidence is determinable from our figures.

The average age incidence in the Bellevue Hospital series was 52.5 years—that of the liver cell type 51.2 years, and that of the bile duct type 54.8 years, no cases occurred in children. Classed according to decades the highest incidence is in the fifth, sixth and seventh decades, as shown in the following table.

TABLE I

| Age Incidence | Liver Cell | Bile Duct | Dual Origin |
|---------------|------------|-----------|-------------|
| 30-39 | 3 | 3 | |
| 40-49 | 12 | 6 | |
| 50-59 | 14 | 4 | |
| 60-69 | 8 | 7 | 2 |
| 70-79 | 1 | 0 | |
| 80-89 | 1 | 1 | |

ANALYSIS OF CLINICAL HISTORY AND PHYSICAL FINDINGS

Clinically, it is impossible to distribute these cases into their respective anatomical groups. An attempt has been made to classify them clinically into one of the following six groups

- 1 Those cases presenting chiefly history and symptomatology of cirrhosis of the liver. This group comprises the largest number (18)
- 2 Those cases presenting chiefly history and symptomatology of disorders of biliary or gastrointestinal tracts. This group comprises the second largest group (14)
- 3 The third group comprises those cases which present signs of a malignant growth at some site in the body characterized, clinically, by loss of weight, weakness, appearance of metastatic nodules elsewhere, etc. In this group are 14 cases, four of which were diagnosed clinically as primary carcinoma of the liver
- 4 Those patients who enter the hospital on the surgical services and die before or shortly after intervention due to spontaneous hemorrhage from a ruptured carcinomatous nodule of the liver. There are three cases in this group
- 5 Those patients whose symptoms and signs do not point to pathological changes in the liver. There are six cases in this group
- 6 Those patients dying before any diagnosis is possible. In this group are seven cases

Many of the cases in one group merge with cases of other groups. This fact explains the difficulty in formulating a clinical picture for a disease which is so variable in its symptomatology.

The majority of these patients entered the hospital with complaints either directly or indirectly referable to the liver. The following analysis shows the variety of complaints together with the average duration of each

| Complaint | Number of Cases | Average Duration of |
|---|-----------------|----------------------------------|
| Vague gastrointestinal symptoms such as dyspepsia, anorexia, occasional vomiting, etc | 20 | 6 weeks |
| Ascites | 19 | 9 weeks |
| Right upper quadrant pain | 16 | 6 weeks |
| Weakness | 10 | 2 months |
| Jaundice | 9 | 4 weeks |
| Edema (dependent) | 5 | 4 weeks (all in liver cell type) |
| Loss of weight | 5 | Unknown |
| Dyspnea | 4 | Indefinite |
| General abdominal pain | 3 | 24 hrs or less |
| Fever | 2 | 1 week |
| Diarrhea | 1 | 7 weeks |
| Hematemesis | 1 | 1 day |
| Metastatic foci | | |
| Enlarged nodes of neck | 1 | 1 month |
| Chest pain | 5 | 1 month |
| Ulcer of eye | 1 | 6 months |

The usual case had two or three major complaints. However, patients with vague gastrointestinal symptoms, right upper quadrant pain (fre-

quently simulating that of cholecystitis) and rapidly accumulating ascites comprise the largest group of cases. Loss of weight as a symptom plays an apparently minor rôle, having been mentioned in only five cases. This may be explained on the basis of the counteracting gain of weight due to ascitic accumulation. Several patients sought medical attention because friends noticed their rapidly increasing girth. Rolleston⁷ reports that two of his patients gained weight. This might well be explained on the basis of ascites. Edema, especially of the dependent sort, was complained of in only five cases, although it was found more frequently on physical examination. It usually appears late in cases of primary carcinoma of the liver and is of differential significance in those patients with complaints referable to cardiac decompensation. Often, it may be difficult to separate the symptomatology of one from the other. This was true in three of the above patients. Fever as a chief complaint was present in two cases only, one in each type of carcinoma. This will be considered in greater detail under clinical findings. Hematemesis occurred once only as did diarrhea. The former fact is of interest because of its higher incidence in uncomplicated cirrhosis of the liver. In primary carcinoma of the liver, the course, as will be emphasized, is much shorter from the onset of symptoms to exitus than is that of cirrhosis of the liver. Collateral circulation is not as well established, therefore, as it is in cirrhosis of the liver.

COURSE

The average course from onset of symptoms to death was 3.2 months. Taken individually, that for the liver cell type was 2.5 months, that for the bile duct type 4.17 months. In ten cases the course was not ascertainable. These figures are unsatisfactory. No definite point of onset of the carcinomatous transformation could be ascertained. In many patients symptoms were masked or so negligible that they were not mentioned. Having no definite point of inception of the malignant process to compute from, the known time of onset of the more severe complaints was used as the criterion from which to estimate the onset of the disease. However, one does learn from these figures that the duration of the illness from the onset of symptoms to death is a short one, more so in the liver cell type than in the bile duct type. The extent of liver involvement seems to be correlated with the length of life. Those patients who show less extensive involvement of the liver pursue a somewhat longer course, as do those in whom the cirrhotic process in the liver is less severe.

ETIOLOGY

Karsner,⁸ reviewing nine cases clinically and pathologically, considered several factors as possible contributing causes, among which were alcohol, tobacco and opiates. Syphilis was not mentioned in any of his cases. In the present analysis it was impossible to consider all these factors inasmuch

as reference to many of them was not made. However, syphilis and alcohol were mentioned either in the affirmative or negative in the majority of instances.

In ten cases of the present series, nine of which were of the liver cell type, indications of syphilis were present, such as positive Wassermann reactions, positive histories and affirmative postmortem findings. In 22 patients a history of overindulgence in alcohol was obtained. Nine were heavy drinkers either in the past or at the time of admission. The remainder of the 22 patients fell in the class of moderate drinkers. In ten cases no information was available on this point. Here also the evaluation can readily be seen to be extremely difficult because of the personal equation involved. The distribution of the cell types was approximately equal. No notation on any of the above cases was made as to the incidence of pellagra, peripheral neuritis or beriberi.

The physical findings varied greatly. In some instances no physical changes referable to carcinoma of the liver were detectable. In others, the findings were more indicative of pathological changes in the liver.

General Appearance In spite of the absence of loss of weight in the majority of the patients, emaciation or signs of poor nutrition were recorded in the greater percentage.

Jaundice Jaundice was present in 32 patients, or in 51.6 per cent, at some time during their hospitalization. It was usually mild in type. There was a noticeably higher incidence of jaundice in the bile duct than in the liver cell type, 57.1 per cent in the former, 46.1 per cent in the latter. This, compared with the incidence of jaundice in cirrhosis of the liver, is higher, that in cirrhosis being less than 30 per cent of all cases at some time in their course, and then usually slight and frequently transient. Jaundice was relatively infrequent in the massive type of primary carcinoma. The reasons for this will be evident after consideration of the naked eye pathological changes.

Ascites Ascites was present in 28 cases, or in 45.2 per cent. The incidence was about equal in both the bile duct and liver cell types.

Hepatomegaly The percentage of patients in whom the liver was either palpable or enlarged on percussion was 70.0 per cent, or in 44 cases. In a large number of patients the presence or absence of nodularity was difficult to determine because of ascites. However, it was mentioned in 28 of the 44 cases. The liver was tender in only five cases. Rolleston states that as a rule, patients with cirrhosis of the liver and carcinoma complain oftener of tenderness than those without carcinoma. This statement is not borne out in the present series where the liver was tender in a minority of patients. Patients with carcinoma complained of pain more frequently, usually located in the right upper quadrant, than those with portal cirrhosis alone. This fact has been mentioned by several writers.

Splenomegaly The spleen was palpable in one case only. This in part was probably due to interference by ascitic accumulation.

Dependent edema was present in eight cases. In all of them there was ascites as well.

Hemoglobin determinations and red blood counts were done in 20 cases. The average in these cases was 73 per cent hemoglobin with 3.41 million red blood cells, the extremes varying from 49 to 96 per cent hemoglobin and 2.51 to 5.1 million red cells. White blood counts were done in 25 cases, the average count being 10,920, the extremes varying from 7000 to 21,800. Icteric indices were done in several cases but no conclusions appear to be justifiable in so small a number of determinations.

Temperature. Fever was observed in 29 cases. This, as a rule, was mild, varying from 99 to 101 degrees Fahrenheit. In four patients in whom the temperature reached a higher level, clinical signs of pneumonia were present. In short, fever was present in 25 patients in whom no findings referable to infection or other source of fever were found. This constitutes 47.3 per cent, inasmuch as nine cases ran no clinical course. This figure is somewhat lower than that reported by others.

PATHOLOGY

Classification. The gross pathological changes in the liver comprise, first, those of the tumor itself and second, those of the associated cirrhosis, when present. According to the classification of Eggel, the 62 cases in this series fall into the three groups as follows:

| | |
|-------------------|--|
| Massive type | 13 cases, nine of which were of liver cell and four of bile duct origin. |
| Multinodular type | 37 cases, 23 of which were of liver cell, 12 of bile duct, and two of dual origin. |
| Diffuse type | 12 cases, six of which were of liver cell and six of bile duct origin. |

The above figures show the preponderance of the multinodular type over the combined diffuse and massive types. A still larger number of cases, however, might well have been classified as of the massive type had it not been for the fact that many small secondary nodules were present in the left lobe of the liver.

Cirrhosis of the Liver. The association of cirrhosis of the liver in these cases is frequent. Eggel reports an incidence of 85 per cent of cirrhosis of the liver in primary liver cell carcinoma, and 59 per cent in the bile duct type. Karsner reports cirrhosis in the nine cases studied by him, four of which were of liver cell origin, and five of bile duct origin. In the present series many cases were diagnosed by the naked eye as combining primary carcinoma and cirrhosis of the liver. However, on microscopic examination several fallacies became apparent. First, as mentioned by Eggel, is the desmoplastic reaction to the tumor growth that is present in both forms, although it is more severe in the bile duct type. In order to ascertain the presence or absence of cirrhosis, one must take sections far enough from the tumor tissue in order to exclude desmoplastic reaction. Second, the

pressure of tumor nodules, together with necrosis of surrounding tissue and subsequent fibroblastic reaction, must be considered in determining the presence of a cirrhotic process. One must examine uninvolved tissue to exclude these factors. Third, biliary obstruction due to tumor encroachment on bile radicles frequently causes fibrosis of liver tissue. In such situations, however, the fibrosis is usually biliary in origin rather than portal.

With the above facts in mind, an attempt was made to ascertain the incidence of cirrhosis of the liver in the present series. In some instances it was impossible to make this decision because of the presence of tumor tissue throughout the liver. These cases were usually of the multinodular type. They were six in number. It was found that 25 of the 39 cases of carcinoma of the liver cell type, or 64.1 per cent, were attended by some degree of cirrhosis, while only seven of 21 cases of bile duct origin, or 33.3 per cent revealed detectable cirrhosis. These figures are somewhat lower than those of Eggel's. His cases, however, were collected in greater part from different sources, and many of them were classified without benefit of microscopic examination.

Microscopic Types of Carcinoma As already mentioned, there are three microscopic types of primary carcinoma of the liver—the liver cell, bile duct and dual or indeterminate.

The liver cell type of carcinoma is composed of strands and cords of large polygonal cells with pinkish cytoplasm and large round vesicular nuclei frequently having one or two nucleoli. These cells are arranged in cords and may even simulate lobules of liver tissue. The cells at the edges of the tumor nodules may frequently be traced in the process of transition from apparently normal liver cells. No central veins are discernible in these tumor nodules, but bile is often present in the intercellular spaces and in the accompanying biliary radicles which, in some instances, show marked proliferation. The formation of giant cells by amitotic division is frequent. There are usually moderate or even marked signs of anaplasia, characterized by variations in the size and shape of the cells as well as in their staining properties. In the majority of these cases tumor invasion of the veins and lymphatics may be detected microscopically.

The bile duct type of tumor, in contrast to the liver cell type, assumes the appearance of an adenocarcinoma, the lining cells varying from low cuboidal to tall columnar, depending on their origin from the smaller or larger biliary radicles. The cytoplasm is usually clear, somewhat basophilic, with round or oval, hyperchromatic nuclei. Nucleoli and giant cells are much less frequent than in the liver cell type. At times the structure of the tumor may vary from simple bile duct proliferation to that of a true adenocarcinoma. There is a more marked desmoplastic reaction in the bile duct than in the liver cell type. As in the liver cell type there is evidence of invasion of veins and lymphatics by tumor tissue.

In both types there is usually moderate lymphocytic reaction in the stroma. This is pronounced in cases associated with cirrhosis of the liver.

The dual or indeterminate type is rare. The fact that in this type differentiation is so irregular suggests a higher degree of malignancy as far as microscopic evidence may be depended upon to estimate the degree of malignancy of any tumor. However, with only two cases from which to draw conclusions, little can be said on this point with any measure of certainty. Both cases in question, however, metastasized to the lungs. This fact supports the view that tumors of dual origin tend in the direction of a somewhat exalted degree of malignancy.

Hemochromatosis No figures on the incidence of hemochromatosis in primary carcinoma of the liver are available. In the present series there were encountered six cases, or an incidence of 9.9 per cent. In all six cases there was an associated cirrhosis of the liver. However, there were only a total of 32 cases in the 62 cases of this series which had cirrhosis of the liver. This, therefore, would give an incidence of 18.7 per cent of hemochromatosis in those cases of primary carcinoma of the liver associated with cirrhosis. The incidence is noticeably higher than that of hemochromatosis in cirrhosis of the liver without primary carcinoma which has been variously reported as occurring in 7 to 10 per cent of all such cases.

Size of Liver The size of the liver was mentioned in 48 of the 62 cases of primary carcinoma in this series. The average was 2900 grams. In four the liver was mentioned as "normal" or "small", in eight as "large" and in one case no mention was made of the size. The average size of the liver in 30 cases of the liver cell type was 2834 grams, while that in 17 cases of the bile duct type was 2990 grams.

Ascites Ascites was present in 45 cases, or in 72.6 per cent—the most constant finding of the series. This varied in amount, averaging three to four liters. The ascites was bloody in six cases, two of which showed superficial necrosis of tumor nodules with rupture and hemorrhage. In seven others ascites was serosanguinous in character.

Splenomegaly Splenomegaly was present in the majority of cases. In 39 of the 62 cases where the weight was mentioned, the average was 354 grams, and was slightly higher in the bile duct type. In 13 cases the spleen was mentioned as "normal" in size, while in six it was "enlarged". No mention of size was made in four cases. It has been said that the incidence of splenomegaly is in direct proportion to that of neoplastic thrombosis of the portal or splenic veins. In 27 cases of the liver cell type analyzed in this paper, the average weight of the spleen was 331 grams. Of these, 11 showed neoplastic venous thrombosis, 10 involving the portal vein (and, in three of them, the splenic vein as well), and in one case intrahepatic venous channels. Sixteen had no naked eye evidence of thrombosis. In one of the 11 cases with venous thrombosis, the spleen weighed 90 grams. In the others it weighed over 150 grams. In 12 cases of the bile duct type the

average weight of the spleen was 380 grams. Neoplastic venous thrombosis was mentioned in three and in all of them the spleen weighed over 150 grams. The heaviest spleen in the entire series weighed 900 grams and showed no naked eye evidence of tumor thrombosis of any part of the portal system. The explanation of the splenomegaly on the basis of portal obstruction is supported by the fact that, on microscopic examination in the majority of cases, venous invasion was evident. This, together with the degree of portal cirrhosis, explains the higher incidence of splenomegaly and ascites in carcinoma than in cirrhosis of the liver alone.

Jaundice The incidence of jaundice was the same clinically and post mortem. Jaundice was explainable in the majority of cases on the basis of biliary obstruction by pressure from tumor nodules. This point is borne out by the infrequency of jaundice in cases of the massive type, that is to say, those which were not attended by secondary nodules. In other instances jaundice was due to widespread destruction of liver tissue by tumor growth.

Metastases The secondary spread of primary carcinoma of the liver takes place by direct extension and by metastasis through the blood and lymph channels. Solitary distant metastases to brain, bone, kidney, etc., are not uncommon. In 19 cases, or in 30.6 per cent, naked eye evidence of neoplastic venous thrombosis was present. In several cases this process involved two or more of the larger venous channels leading to or from the liver. In six of the 19 cases there were visceral metastases likewise visible to the naked eye. The tumor thrombi were not adherent to the wall of the vessel but were composed of organized and laminated blood clot in which were strands and masses of tumor tissue. In two cases, tumor thrombi were found to have travelled through the inferior vena cava into the right auricle of the heart. In several, the splenic vein was thrombosed throughout its entire length. In 29 cases, or in 46.8 per cent of the entire series, there was no naked eye evidence of metastasis. In the remaining 33 the sites of metastases were numerous. The most frequent were the periportal lymph nodes and the lungs, especially the right lung. The reason for this is evident when one appreciates the frequency of venous and lymphatic invasion by these tumors. On the contrary, it is amazing that so many cases exhibit freedom from metastases in spite of the high incidence of venous and lymphatic neoplastic invasion.

The following table shows the sites of metastases in both types.

In connection with the general subject of metastasis in primary carcinomata of the liver, it is interesting to note that Bolker⁹ and his associates recently reviewed the literature with especial reference to the occurrence of bone metastases. They found only nine such cases recorded. In the present series three examples of metastasis to bone were noted. In one case the metastases were multiple and involved ribs, vertebrae and the left orbital bone, in the other two ribs alone were involved. In another case of this series the spleen was invaded by retrograde growth through the splenic

| | Liver Cell Type | Bile Duct Type | Total |

| Eye | 1 | 0 | 1 |

vein The size of the spleen was not mentioned Involvement of the heart muscle occurred once by direct extension through the pericardium from a metastasized mediastinal node

COMMENT

Only seven of the above 62 cases were diagnosed clinically The diagnoses entertained in order of frequency were (1) carcinoma of the stomach with metastasis to the liver, (2) cirrhosis of the liver, (3) carcinoma of the head of the pancreas, (4) "malignancy" of the liver, primary site undetermined, (5) cardiac decompensation In the remaining 55 cases there is no available data to show that the possibility of primary carcinoma of the liver was even suggested It would seem that the diagnosis should be made more often if its relative frequency is borne in mind Symmers, at Bellevue Hospital, correlating 20 years' experience in the necropsy rooms and in the wards, has successfully made the clinical diagnosis in seven instances based on the following criteria

- (1) A male patient over thirty-five years of age
- (2) A large palpable tumor mass in the right lobe of the liver
- (3) No primary tumor discoverable elsewhere
- (4) Jaundice, usually mild
- (5) Ascites
- (6) An otherwise unexplainable fever of mild degree

It was found that each of the 62 cases fulfilled at least four of the above criteria and in the majority of cases five or even all of them The author believes that a history of either vague gastrointestinal nature of short dura-

tion or signs of portal obstruction in the form of rapidly accumulating ascites should be used as additional information

The history of rapidly accumulating ascites in primary carcinoma of the liver is in contra-distinction to that of ascites due to other causes—cardiac failure, tuberculosis or carcinomatosis of the peritoneum, etc. In ascites of cardiac origin evidence of its cause is practically always available. In ascites of peritoneal origin due to carcinoma, tuberculosis or the like, findings indicative of its cause are likewise apt to present themselves. On the other hand rapidly accumulating ascites may be due to thrombosis of the portal vein of variable origin. In this connection it is to be recalled that neoplastic thrombosis of the portal vein not infrequently occurs in association with primary carcinoma of the liver.

SUMMARY AND CONCLUSIONS

1 Primary carcinoma of the liver, formerly regarded almost in the light of a curiosity, is shown in this paper to occur once in every 394 necropsies, an incidence of 0.25 per cent based on 24,400 consecutive necropsies performed at Bellevue Hospital over an unbroken period of 30 years. The Bellevue series consists of 62 cases, in every one of which the diagnosis was verified by microscopic examination. It is believed to be the largest series thus far derived from a common source.

2 Primary carcinoma of the liver is a clinical and pathological entity susceptible of diagnosis during life.

3 The clinical diagnosis may be postulated with reasonable certainty on the following criteria (Symmers): (a) the presence of a palpable massive solitary growth in the right lobe of the liver in a male over 35 years of age, (b) inability to determine a primary growth in any other part of the body, (c) jaundice, usually of a mild grade, (d) ascites and (e) a low degree of otherwise unexplainable fever. In addition to these criteria a preliminary history of vague gastrointestinal disturbances of short duration or signs of portal obstruction extending over a period of a few weeks only, should likewise be taken into consideration (Gustafson). Clinically, the disease pursues a rapid course, death occurring, as a rule, within three to four months after the onset of detectable symptoms and signs.

4 In the Bellevue series of 62 cases of primary carcinoma of the liver, 32, or 51.6 per cent were associated with cirrhosis of the liver, including six cases of hemochromatosis of the liver with cirrhosis.

5 Microscopically, 39 of the 62 cases studied at Bellevue Hospital were obviously derived from the liver cells and 21 from the bile ducts, 2 were of indeterminate or dual origin. The liver cell type is characteristic. It has multiple points of origin and its cell constituents may be traced directly into neighboring apparently normal parenchyma cells. The bile duct type, as should be expected, is histologically indistinguishable from the duct cell carcinoma of the pancreas.

THE CLINICAL USE OF CRYSTALLINE INSULIN *

By SAMUEL S. ALTSHULER, M.D., F.A.C.P., *Eloise, Michigan*

SINCE the discovery of insulin by Banting and Best,¹ unremitting effort has been put forth toward the improvement of the product. One of the lines of endeavor has been to make insulin purer by crystallization.

Insulin was first crystallized by Abel^{2, 3, 4} in 1926. He prepared it from highly purified commercial preparations. Howard and DeLawder⁵ were the first to determine whether this crystalline insulin could be used therapeutically in human beings for the treatment of diabetes mellitus. Four diabetic patients were carefully regulated on diets and standard insulin, then crystalline insulin was substituted for standard in equivalent doses. They observed no appreciable difference except for a slight increase in carbohydrate tolerance which they thought could be expected in diabetic patients under treatment.

Until recently crystalline insulin was not used clinically because the yield of this insulin was small and it was therefore not commercially practical. In February of 1936, however, a new method of crystallizing insulin was developed by Dr. Melville Sahyun, of Detroit, which was practical for commercial use. We had the opportunity of making clinical trials of this crystalline insulin and found it to be suitable for the treatment of diabetes.⁶

Comparative studies were then made of standard commercial and of crystalline insulin. These studies were conducted with 20 patients and the conclusions were that crystalline insulin could be used in the treatment of diabetes mellitus and that with its use the blood sugar levels could be controlled with fewer doses and fewer units of insulin than was the case with standard insulin. Freund and Adler,⁷ Mains and McMullen,⁸ and Barach⁹ have reported similar results.

During the past year we have used crystalline insulin in the treatment of 100 diabetic patients who range in age from six to 86 years and who present a variety of complications. Some of these patients were being treated in the hospital as in-patients, some were treated in the clinic as out-patients, and the rest were private patients seen in the office.

The results of this year's work are summarized in tables 1 and 2. The former shows the number in each age group and the incidence of complications, the latter, the various types of complications present.

It is well known that in children and adolescents the treatment of diabetes with diet and standard insulin abounds in difficulties. The attempt to keep the blood sugar within normal limits necessitates a great deal of adjustment of amount of insulin and time of administration to prevent hypoglycemic reactions.

* Read at the St. Louis meeting of the American College of Physicians, April 22, 1937.

TABLE I
One Hundred Diabetic Patients to Whom Crystalline Insulin Was Given

| Age Group | With Complications | Without Complications | Total |
|-------------|--------------------|-----------------------|-------|
| 1-20 | 2 | 8 | 10 |
| 21-40 | 5 | 14 | 19 |
| 41-60 | 39 | 7 | 46 |
| 61 and over | 15 | 10 | 25 |
| Totals | 61 | 39 | 100 |

TABLE II
Types of Complications Present in Diabetic Patients in This Study

| | |
|---------------------|---|
| Infections | Respiratory Lues Tuberculosis Osteomyelitis Carbuncle Ulcers of legs Acute iritis |
| Cardiovascular | Hypertension Cerebral hemorrhage Hemiplegias Coronary thrombosis Heart disease Hypertensive Arteriosclerotic Rheumatic Gangrene |
| Gastrointestinal | Peptic ulcer |
| Neurological | Neuritis Epilepsy Parkinson's disease |
| Ophthalmological | Cataracts Neuroretinitis with blindness |
| Other complications | Pregnancy Acidosis Uremia Pre-operative and post-operative |

The 10 patients in our youngest group, those under 20 years of age, were successfully treated with crystalline insulin. Two were controlled with one dose daily, eight were controlled with two doses administered from 10 to 12 hours apart, the morning dose given one-half to one hour before breakfast and the evening dose either before or after the evening meal according to the individual indications. Seven of these children were attending school, and elimination of the noon dose of insulin—and in one case of a midnight dose also—was greatly appreciated. In this group two of the patients presented complications. A boy of seven had an active childhood tuberculosis with a daily rise in temperature. A girl of 19 had an infection of

the right index finger with osteomyelitis of the distal phalanx, due to a needle prick

The second group, 21 to 40 years of age, included wage-earners and housewives. All of the patients in this group were given crystalline insulin in two doses, at 10 to 14 hour intervals. The advantage of being able to go without a noon dose is very obvious in the cases of persons working in factories or offices. One of the young women in this group has pulmonary tuberculosis and she had found it a great hardship to have her sleep interrupted nightly for a 1 a m dose of insulin. With crystalline insulin, however, she has been able to keep her diabetes under control with two doses given 14 hours apart—at 8 a m and 10 p m.

The age group from 41 to 60 years included a good many patients manifesting various types of arteriosclerotic complications—coronary heart disease, hemiplegias, ophthalmoplegia, blindness due to vascular changes, hypertension and gangrene. There were also some other types of complications—cataracts, lues, tuberculosis and acute iritis. Arteriosclerotic manifestations were also present in the group from 61 to 86 years of age.

In the care of elderly diabetic patients with cardiovascular complications, it is especially important to prevent hypoglycemic reactions. Rapid reduction of the blood sugar level in this type of patient has been the cause of cerebral thrombosis, coronary thrombosis, visual disturbance due to thrombosis in the vessels of the fundi, and thrombosis in the peripheral vessels of the extremities. It would be difficult to estimate the mortality rate for the unskillful use of insulin. For this reason, in making clinical studies of insulins, it is just as important to judge the control of the diabetes from the standpoint of hypoglycemia as from that of hyperglycemia and glycosuria.

We have used crystalline insulin successfully pre-operatively and post-operatively in two cases, and also in the cases of three patients with acidosis. In these conditions, where glucose was administered every four hours either by mouth or intravenously, crystalline insulin was given every eight hours and the doses were determined by urine and blood examinations.

Crystalline insulin is administered subcutaneously in one or two doses. The morning dose is given one-half to one hour before breakfast and the second dose—if such is necessary—is given 10 to 14 hours later, either before or after the night meal depending upon the circumstances of the patient's eating arrangements. In a patient whose insulin requirement is unknown, we start with an arbitrary amount, 10-0-10, and adjust the dose according to the urine and blood examinations. If the patient had previously been on standard insulin, he is started on two-thirds of that amount of crystalline insulin divided into two doses.

In the entire group of patients to whom crystalline insulin has been given it has been noted that when there is an insulin reaction it comes about gradually unassociated with any shock. An opportunity afforded itself to note comparative shock effects of standard and of crystalline insulin in a

study of the use of insulin in the treatment of schizophrenia by our psychiatric department. Four non-diabetic schizophrenic patients were given insulin to produce shock. Sixty to 80 units of standard insulin produced a severe shock in all four patients, but 100 units of crystalline insulin did not cause any shock to three of the patients, and resulted, in the case of the fourth patient, in a light coma which was very readily relieved. Another observation was that with crystalline insulin it was possible to produce much lower blood sugar levels without resulting coma than was possible with standard.

Among the patients to whom crystalline insulin was administered no local reactions were observed. Ordinarily such reactions, which are considered allergic, may be expected in about 5 to 10 per cent of diabetic patients treated with insulin. It has been reported that crystalline insulin Abel¹⁰ and crystalline insulin Scott¹¹ have caused allergic reactions in certain sensitive individuals but much less so than noted with the standard commercial preparations. Perhaps after we have used crystalline insulin in a larger number of cases, we may also encounter allergic reactions. Crystalline insulin is a protein and therefore might cause reactions, but being a purer pancreatic extract, it is less likely to contain other pancreatic proteins than is standard insulin.

The condition of lipodystrophy which is noted occasionally at the site of insulin injection was present in three of our patients, and was very marked in two, producing deformed looking arms and thighs. The use of crystalline insulin over a period of 18 months has not produced this subcutaneous atrophy of the tissues in these patients.

From a year's experience with crystalline insulin, we have concluded that it can be used in any type of diabetes requiring insulin, with or without complications, except in diabetic coma with which condition we have not had any experience. Crystalline insulin is remarkably stable. We observed no clinical evidence of deterioration in a solution kept at room temperature for as long as a year.

Since Abel first crystallized insulin, studies have been made of its physiological, physical and chemical properties. Some of the findings offer a possible explanation for the greater efficiency of crystalline than of standard insulin. Observations have been recorded of a preliminary hyperglycemia following the injection of standard insulin, which led to investigations to determine whether this hyperglycemic action is a property of insulin or whether there is a secondary accompanying substance in the insulin. Burger and Kramer,¹²⁻²¹ who have made a large number of chemical and physical comparative studies, believe that they have been able to isolate a hyperglycemic principle from standard insulin which they call Glukagon. Their studies show that this principle is not present in crystalline insulin. Geiling and DeLawder²² investigated this point and concluded that the hyperglycemic action was due solely to impurity and that crystalline insulin did not

produce any preliminary hyperglycemia because of the absence of this impurity Tangl and Than²⁹ confirmed the presence of such impurities in standard insulin by isolating a pancreatic extract possessing marked hyperglycemic properties

Thus, evidence points to the presence of a substance in standard insulin, whether it be a separate hormone or an impurity, which causes hyperglycemia, and so obviously must decrease the efficiency of the insulin This substance is not present in crystalline insulin This seems a logical explanation of the greater efficiency of crystalline insulin than of standard

SUMMARY

Crystalline insulin has been used in the treatment of diabetes in 100 patients ranging in age from 6 to 86 years Sixty-one of these patients had various types of complications, 39 were without complications In some of these patients the diabetes was well controlled with one dose of crystalline insulin None of them required more than two doses which were administered 10 to 14 hours apart

Insulin reactions were rare, and when they did occur were not associated with as much shock as is experienced with standard insulin, much lower blood sugar levels were obtained without manifest symptoms of reaction No local reactions were observed in this entire group The condition of lipodystrophy, which was present in three patients following the use of standard insulin, was not observed when crystalline insulin had been in constant use for 18 months

Possible explanations for the increased efficiency of crystalline insulin are presented

ELECTROCARDIOGRAPHIC CHANGES FOLLOWING EXTERNAL CHEST INJURY TO DOGS^{*}

By R W KISSANE, M D , F A C P , R S FIDLER, B A , M D , and R A
KOONS, B A , M D , *Columbus, Ohio*

MEDICAL literature contains considerable evidence, obtained by autopsy, that non-penetrating wounds to the chest can produce severe traumatic lesions in the pericardium, heart and great vessels, but it is not generally accepted that less severe trauma can cause mild changes in the heart which have a tendency to recover

Beck¹ described experiments on dogs where the heart was exposed and contused. The resultant myocardial injuries produced electrocardiographic changes similar to those obtained in coronary artery occlusion, affecting chiefly the Q- and T-wave and having a tendency to return to normal. Randles, Gorham and Dresbach² described alternation in the RS-T component of the electrocardiogram simulating those associated with coronary artery occlusion, produced in dogs by experimental auricular rupture and the resulting hemopericardium. It was their opinion that the variation of the RS-T component was due to the amount of fluid in the pericardial sac and not the auricular injury.

In order to ascertain whether electrocardiographic changes do occur following external chest injury, and if so, the type of changes, the speed with which they occur, the amount of required trauma and the lesions produced, a series of experiments was performed on dogs in which electrocardiographic and pathological studies were made following varying degrees of injury to the chest but not to the heart direct.

• PROTOCOLS

Dog 1 (figure 1) A young mongrel dog, weight 30 pounds, was given 1 gm of sodium amytal intraperitoneally and one hour later the control electrocardiogram *A* was taken. A $\frac{3}{4}$ inch board was placed over the sternum and one heavy blow was struck with a hard rubber mallet and electrocardiogram *B* was taken in five minutes. Ten minutes after the first blow, a second similar blow was struck in the same manner. This was followed by a jerky type of respiration using chiefly the external thoracic muscles. Electrocardiogram *C* was taken 10 minutes after, *D*, 20 minutes after, *E*, one and one-half hours after, *F*, two and one-half hours after, and *G*, five and one-half hours after the second blow. At this time the dog was killed by chloroform and an autopsy performed which revealed hemorrhage into the anterior and posterior mediastinal spaces and about the roots of both lungs. The microscopic examination revealed hemorrhagic infiltration of the lungs, a small hemorrhage beneath the endocardium at the base of the mitral valve and a small hemorrhage beneath the endocardium of one of the cusps of the pulmonary valve.

^{*} Presented at the St. Louis meeting of the American College of Physicians, April 23, 1937.

From the Cardiological and Pathological Departments of White Cross Hospital and the Medical College of Ohio State University, Columbus, Ohio.

Dog 2 (figure 2) A mongrel bitch, weight 35 pounds, was given 1 gm of sodium amytal intraperitoneally and one hour later the control electrocardiogram *A* was taken. A $\frac{3}{4}$ inch board was placed over the upper sternum and two moderately heavy blows were struck with a hard rubber mallet and electrocardiogram *B* was

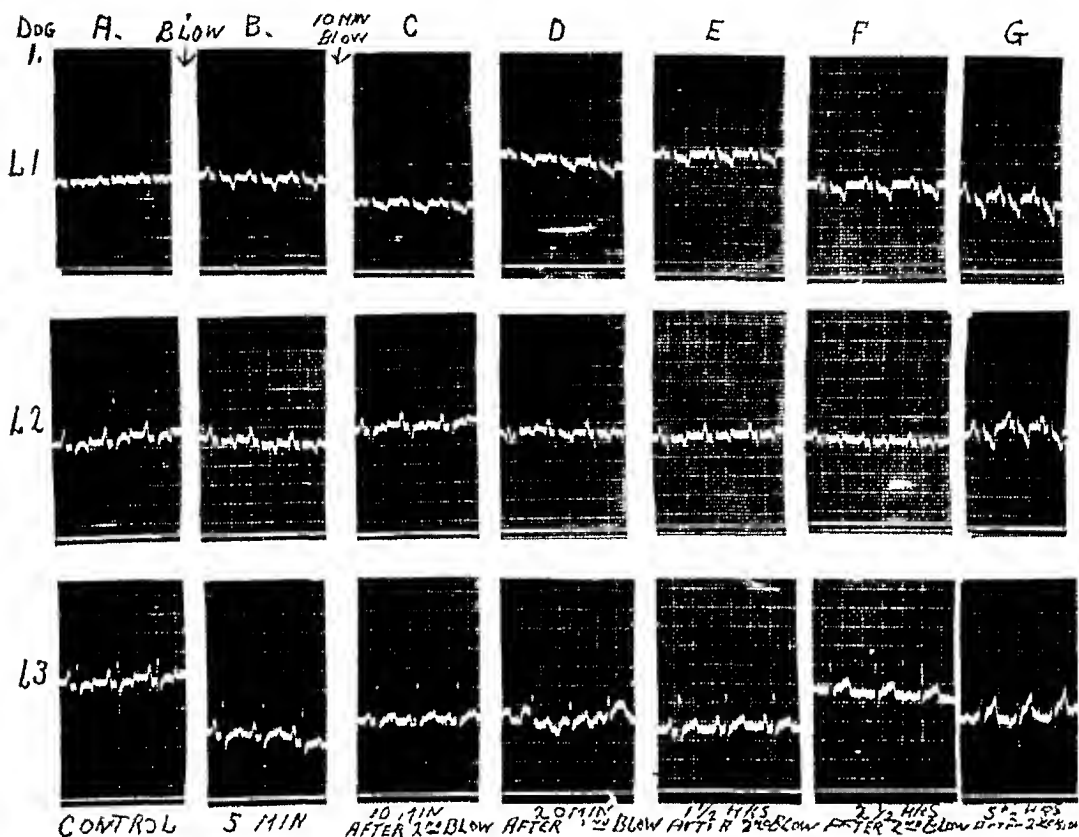

FIG 1 Dog 1

taken in 10 minutes, *C* in one hour, *D* in three hours and *E* in five hours. At this time another similar blow was struck and electrocardiograms *F*, *G* and *H* were taken 10 minutes, one-half hour and three-quarters hour later. At this time the animal was killed by chloroform and an autopsy performed which revealed no abnormal lesions of the heart but moderate atelectasis, congestion and a slight amount of hemorrhage of both lungs.

Dog 3 (figure 3) A young mongrel dog, weight 30 pounds, was given 1 gm of sodium amytal intraperitoneally and one hour later the control electrocardiogram *A* was taken, the sternum was now struck a heavy blow with an ordinary hammer and electrocardiograms *B*, *C* and *D* were taken five minutes, one-half hour and three-quarters hour later. At this time a second similar blow was struck and electrocardiograms *E* and *F* were taken in five minutes and in one hour. A third series of two similar blows was now struck and following these electrocardiograms *G* was taken in one-half hour and *H* in one hour. The animal was now killed by chloroform and an autopsy performed which revealed moderate hemorrhage and atelectasis about the right lung root.

Dog 4 (figure 4) A mongrel dog, weight 25 pounds, was given 0.75 gm of sodium amytal intraperitoneally and one hour later the control electrocardiogram *A*

was taken. A $\frac{3}{4}$ inch board was placed over the sternum and a heavy blow was struck with a 10 pound sledge hammer and electrocardiograms *B*, *C*, *D* and *E* were taken five minutes, one-half hour, one and one-half hours and two and one-half hours later. The animal was killed by chloroform and an autopsy performed that revealed small subendocardial hemorrhages into the right and left posterior cusps of the aortic valve.

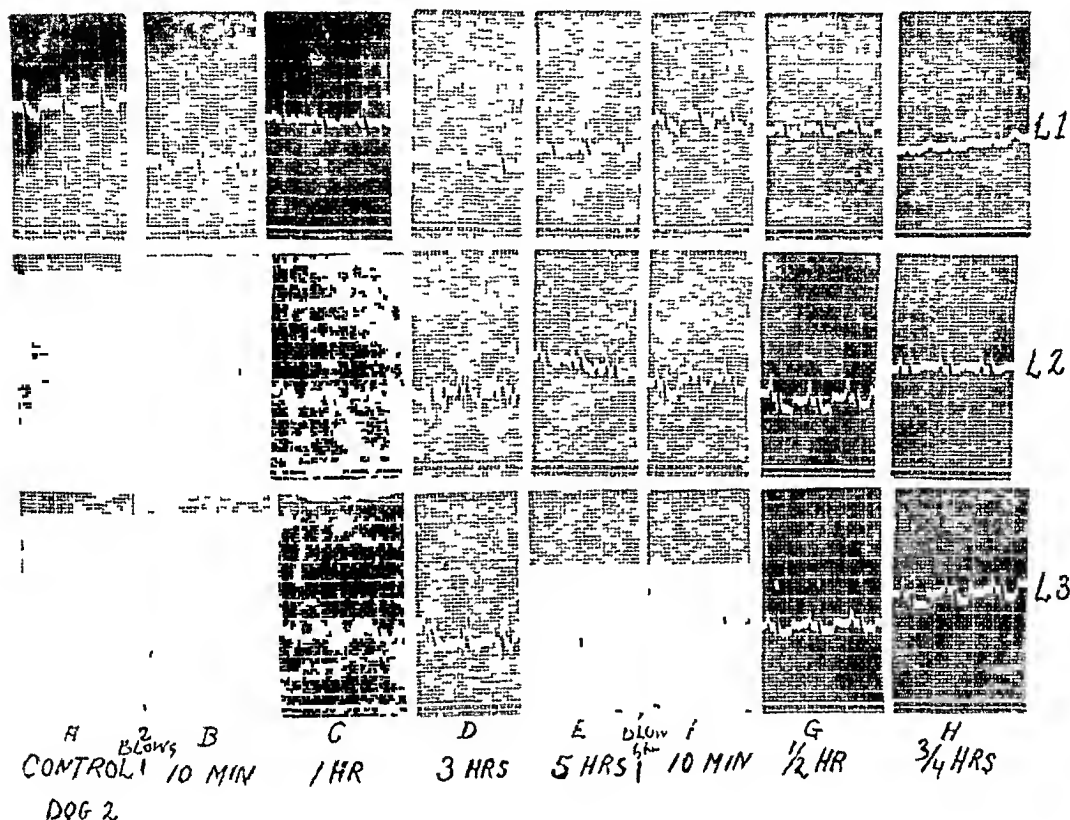

FIG 2 Dog 2

Dog 5 (figure 5) A young mongrel bitch, weight 24 pounds, was given 1 gm of sodium amytal intraperitoneally and one hour and 15 minutes later the control electrocardiogram *A* was taken. A $\frac{3}{4}$ inch board was placed on the left chest over the point of maximal intensity of the apex beat and one full blow delivered with a 10 pound sledge hammer while the electrocardiogram was attached in Lead II with the camera running. The string was protected for only a second while the blow was struck, and immediately afterwards brought back into the camera field and standardized, revealing by the timer that electrocardiogram *B* was taken twelve seconds after the blow was struck (figure 6). Electrocardiogram *C* was taken in five minutes, *D* in one-half hour, *E* in one hour, and *F* in one and one-half hours after the blow was struck. Five minutes after the last electrocardiogram was taken a second blow was delivered in the same manner and the electrocardiogram *G* (figure 7) was taken within a few seconds. Electrocardiogram *H* (figure 8) was taken in 10 minutes, *I* in one and one-quarter hours, *J* in one and one-half hours, and *K* in two and one-half hours after the second blow. At this time the dog was killed by chloroform and an autopsy performed which revealed the peritoneal cavity filled with recent hemorrhage.

originating from two tears in the liver, one in the dome of the right lobe which was 3 cm long, 1 cm wide and 2 cm deep, and another upward from the gall-bladder 3 cm and extending through the entire thickness of the liver at this point. There was no free hemorrhage in the pericardial sac but hemorrhage into the parietal wall of the pericardium anteriorly and into the tissues about the base of the heart. The microscopic examination did not reveal any abnormal lesions.

FIG 3 Dog 3

Dog 6 (figure 9) A mongrel dog, weight 60 pounds, was given 15 gm of sodium amytal intraperitoneally and one and one-half hours later the control electrocardiogram *A* was taken. A 1/4 inch board was placed over the left chest of the dog and one hard blow was struck with a four pound hammer, and one minute later electrocardiogram *B* was taken. Fifteen minutes after the first blow electrocardiogram *C* was taken and a minute later another blow was struck in the same manner, then one minute after the second blow electrocardiogram *D* was taken. Fifteen minutes after the second blow electrocardiogram *E* was taken, and one minute later two blows were delivered in the manner described and electrocardiogram *F* was taken one minute after the third series of blows. After a 15 minute period electrocardiogram *G* was taken and again, one minute later, two more blows were delivered in the manner described and the electrocardiogram *H* was taken in one minute, and *I* in 15 minutes after this fourth series of blows. At this time the dog, still under anesthesia, was taken to a veterinary hospital where he shortly regained consciousness but was found dead in his cage 10 hours later. At autopsy there was found a clean-cut one inch tear in the anterior parietal pericardium, with a moderate amount of free

hemorrhage in the pericardial sac, and a four inch rent in the posterior part of the right diaphragm. There was a contusion with a marked degree of hemorrhage of the entire right lung and of the base of the left lung. Shortly before the dog died the respiration was very rapid and shallow, temperature 106° , heart sounds normal, but many moist rales were heard throughout the chest. Microscopic examination revealed moderate atelectasis and hemorrhagic infiltration of the lungs.

DOG #4

FIG 4 Dog 4

Dog 7 (figure 10) A hound dog, weight 35 pounds, was given 0.75 gm of sodium amytal intraperitoneally and one hour later the control electrocardiogram *A* was taken. One hard blow was struck with a five pound hammer to the point of maximal cardiac pulsation on the left chest, and after 25 minutes electrocardiogram *B* was taken, and after two hours electrocardiogram *C* was taken. The dog was now taken to a veterinary hospital. There was no increase in the respirations nor any elevation of temperature, and the heart sounds appeared normal. The next day the dog was up and about, and appeared normal. There were no signs of tenderness on the chest wall. On the sixth day electrocardiogram *D* was taken and on the seventh day the dog coughed and spit blood, passed blood in the stool and had five attacks of syncope. On the eighth day electrocardiogram *E* was taken, and on the twenty-first day electrocardiogram *F* was taken. At this time the veterinarian reported that following exercise the dog would have an irregular heart rhythm.

DOG #5.

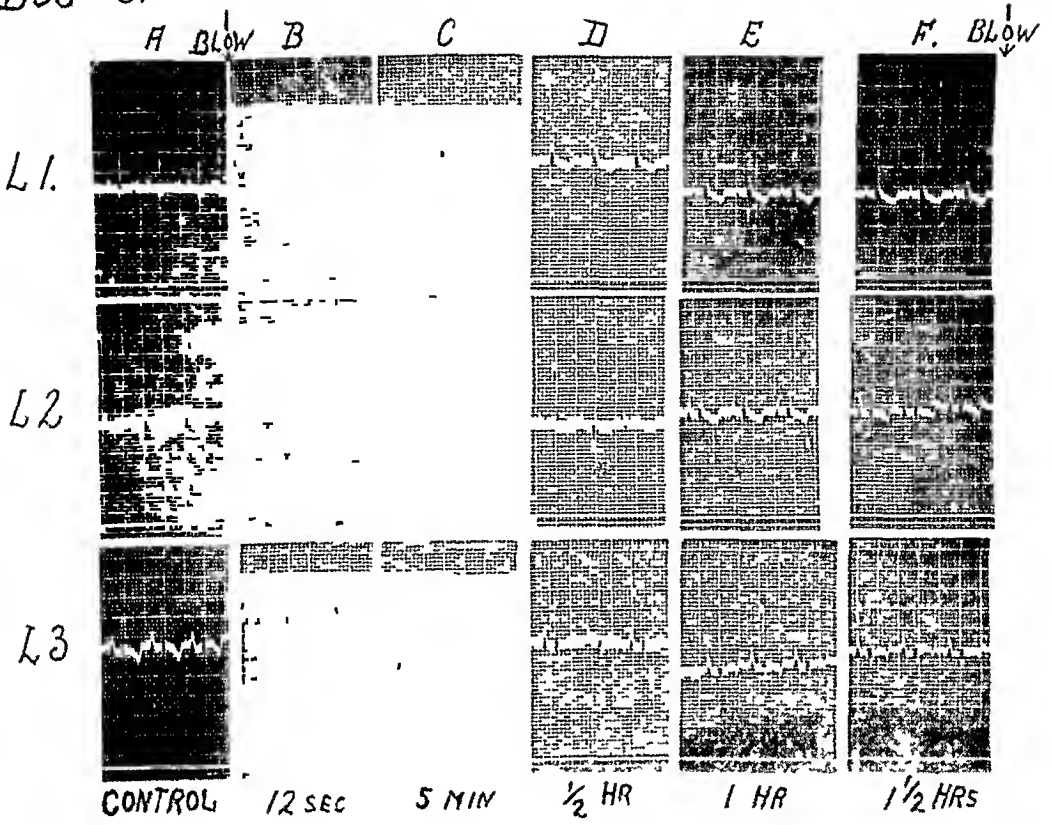

FIG 5 Dog 5

DOG #5

FIG 6 Dog 5 A (control) is the same as A in figure 5 B, 12 seconds after blow, same as B in figure 5

Electrocardiogram *G* was taken on the fortieth day and *H* on the one hundredth day after the blow was delivered, and on the one hundred and twenty-first day the dog suddenly dropped dead. An autopsy revealed no gross abnormal lesions except that the anterior parietal pericardium was slightly thickened. A microscopic examination revealed partial atelectasis, slight congestion and moderate hematogenous pigmentation of the lungs. The left coronary artery showed moderate subintimal and medial thickening with a vacuolization and loss of elastic tissue fibers.

FIG 7 Dog 5 Lead II taken first, Lead I second and Lead III last

Dog 8 (figure 11) A short haired mongrel bitch, weight 22 pounds, was given 0.50 gm of sodium amytal intraperitoneally and one hour later the control electrocardiogram *A* was taken. Following this two hard blows were struck with a five pound hammer on a $\frac{1}{4}$ board placed over the area of maximum intensity of the apex beat on the left chest, and one minute later electrocardiogram *B* was taken. At this time respiration ceased for a short period and then started with an irregular rhythm. Twenty minutes after the blows were struck electrocardiogram *C* was taken, and 50 minutes after electrocardiogram *D*. The dog was then taken to the veterinary hospital. The next morning she was up and about, apparently normal. On the second day after the start of the experiment electrocardiogram *E* was taken, and on the third day the animal died during sleep. An autopsy revealed no injury to the anterior chest wall, though there was a small hole in the anterior pericardium with about 5 cc of blood in the pericardial sac. There was no hemorrhage in the anterior or posterior mediastinal spaces, and a microscopic examination did not reveal any abnormal lesions.

Dog 9 (figure 12) A hound bitch, weight 26 pounds, was given 0.75 gm of sodium amytal intraperitoneally and 45 minutes later the control electrocardiogram *A*

was taken, and following this two hard blows with a five pound hammer were struck on a $\frac{1}{4}$ inch board placed over the area of maximum intensity of the apex beat on the left chest. One minute after these blows electrocardiogram *B*, and 45 minutes after electrocardiogram *C* were taken. The animal was then taken to the veterinary hospital, and the next morning she was up and about, apparently normal. On the seventh day after the start of the experiment electrocardiogram *D* was taken, and on the sixteenth day the animal was found dead. An autopsy did not reveal any gross

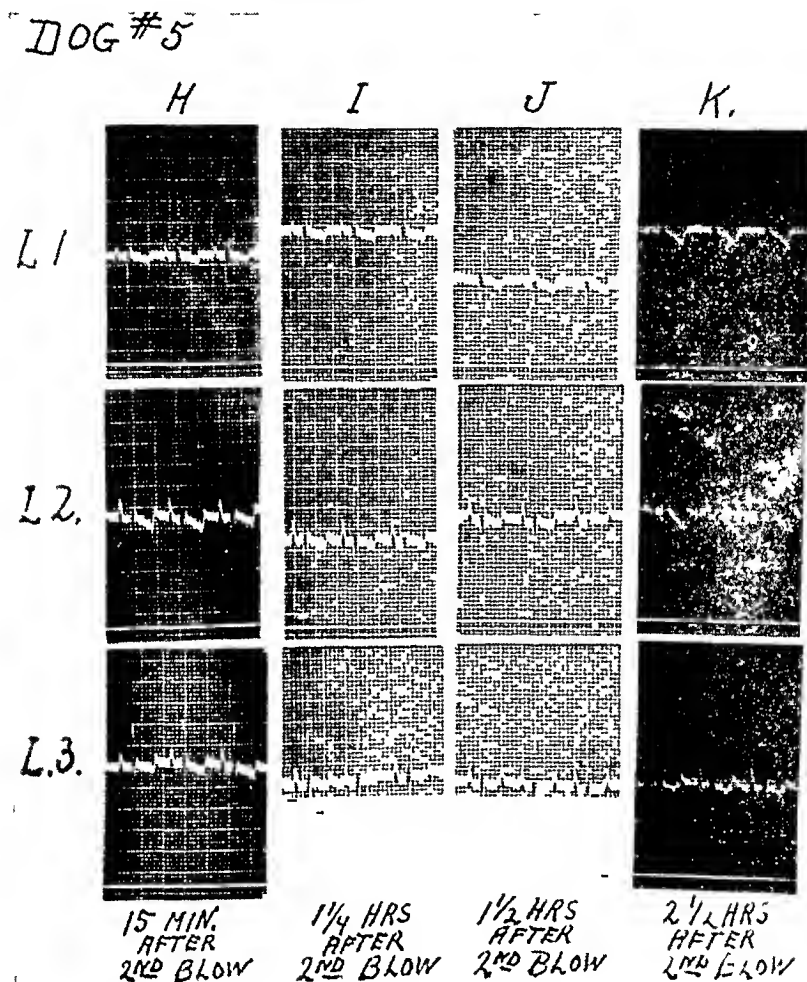

FIG 8 Dog 5

abnormal lesions, and a microscopic examination showed moderate congestion of the lungs and a moderate number of heart failure cells.

Dog 10 (figure 13) A German Shepherd bitch, weight 45 pounds, was given 15 gm of sodium amytal intraperitoneally, and one hour later the control electrocardiogram *A* was taken. Two hard blows with a five pound hammer were struck directly on the area of maximum intensity of the cardiac apex beat on the left chest and electrocardiogram *B* was taken in one minute, *C* in two minutes, *D* in three minutes, *E* in four minutes, *F* in five minutes, *G* in seven minutes (figure 14), *H* in eight minutes, *I* in 12 minutes, *J* in 13 minutes, *K* in 14 minutes, *L* in 15 minutes, and *M* in 16 minutes following the blows. At this time the animal died and an autopsy

Dog 6

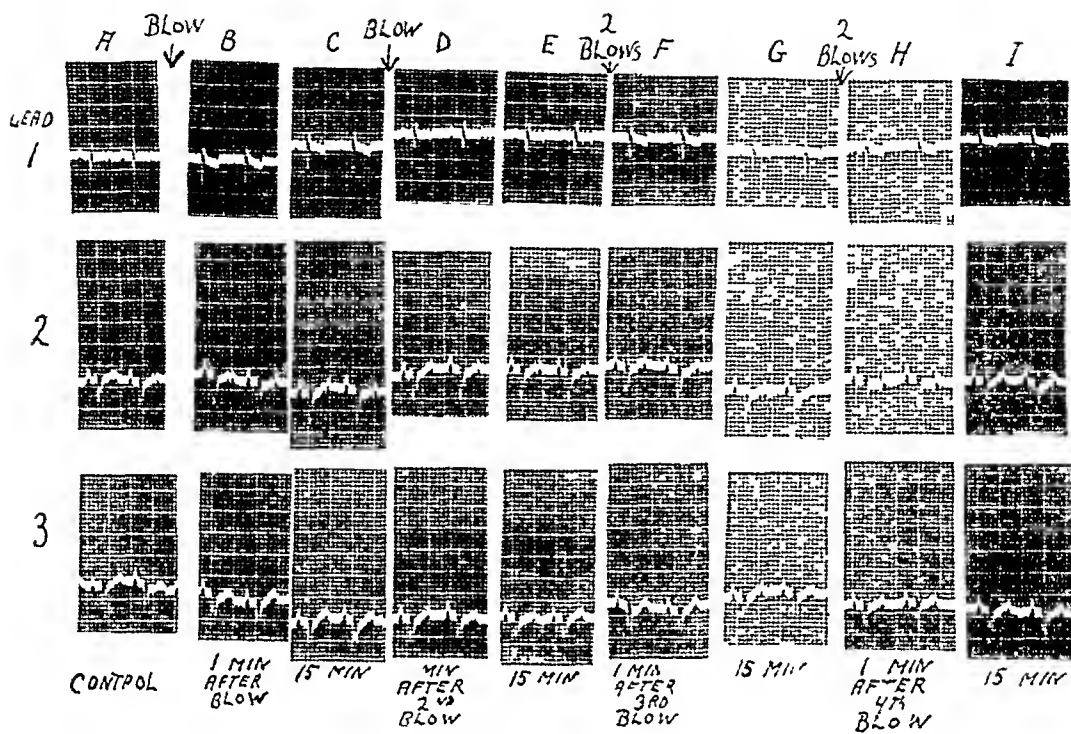

FIG 9 Dog 6

Dog #7

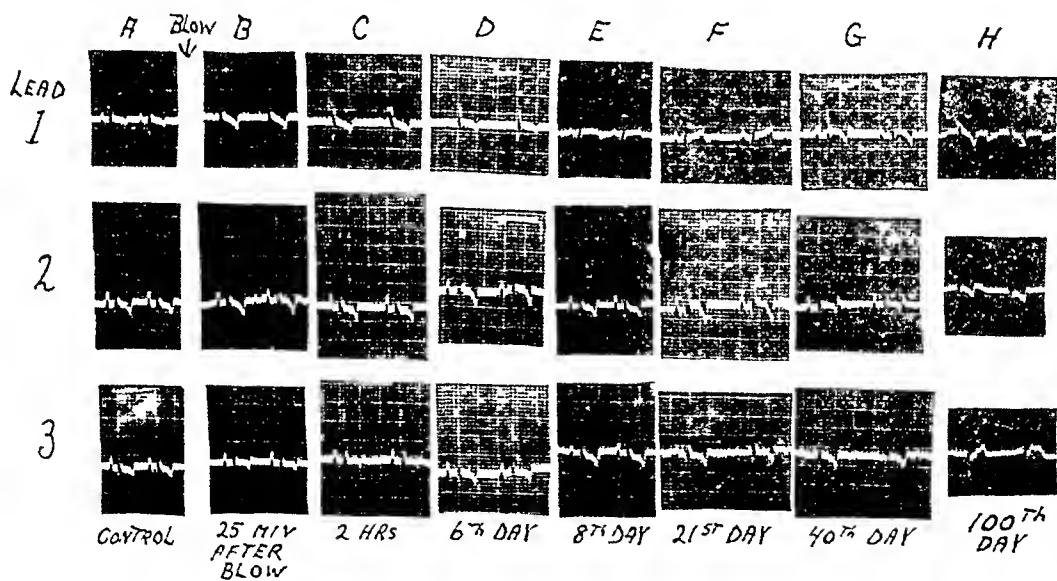

FIG 10 Dog 7

was performed. Gross and microscopic examinations did not reveal abnormal lesions.

Dog 11 (figure 15) A mongrel bitch, weight 17 pounds, was given 0.5 gm sodium amytal intraperitoneally, and one hour later control electrocardiogram *A* was taken. Immediately afterwards one hard blow was struck with a five pound hammer on the area of maximum intensity of the apex beat on the left chest wall. Following this blow electrocardiogram *B* was taken in two minutes, *C* in three minutes, *D* in four minutes, *E* in six minutes (figure 16), *F* in eight minutes, *G* in 11 minutes, *H* in 14 minutes, and *I* in 21 minutes (figure 17), at which time the animal died. An autopsy was performed, but gross and microscopic examinations failed to reveal any abnormal lesions.

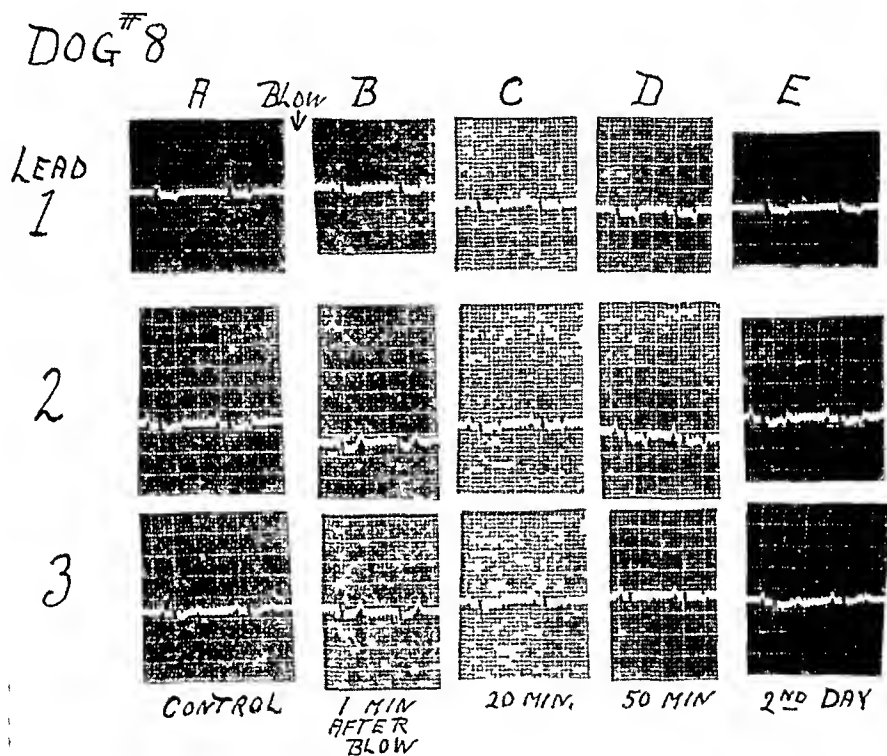

FIG 11 Dog 8

Dog 12 (figure 18) A short-haired mongrel bitch, weight 15 pounds, was given 0.5 gm of sodium amytal intraperitoneally and one hour later the control electrocardiogram *A* was taken. One heavy blow with a 10 pound hammer was delivered to the left chest of the animal, and one minute later electrocardiogram *B* was taken, and four minutes later electrocardiogram *C* was taken. At this time another blow of the same type was struck (figure 19), and in one minute electrocardiogram *D* and in nine minutes electrocardiogram *E* were taken. A similar blow was again delivered, and following this electrocardiogram *F* was taken in one minute, *G* in three minutes, and (figure 20) *H* in 13 minutes. Again a similar blow was delivered and following this electrocardiogram *I* was taken in one minute and *J* in four minutes at which time the animal died. An autopsy was performed which revealed free blood in both pleural cavities, hemorrhage in the anterior and posterior mediastinal spaces, contusion of the entire right lung with a small marginal rupture of both this and the left

lung There was hemorrhage about the base of the heart and a three inch rupture in the parietal pericardium anteriorly where it joins the great vessels, with a small amount of free hemorrhage in the pericardial sac There was an area of contusion one inch in diameter, with hemorrhage in the anterior wall of the right auricle close to the superior vena cava Microscopic examination revealed slight hemorrhage beneath the visceral pericardium of the right auricular myocardium and moderate hemorrhage of the lungs

Dog 13 (figure 21) A short-haired mongrel dog, weight 25 pounds, was given 0.75 gm sodium amytal intraperitoneally, and one hour later the control electro-

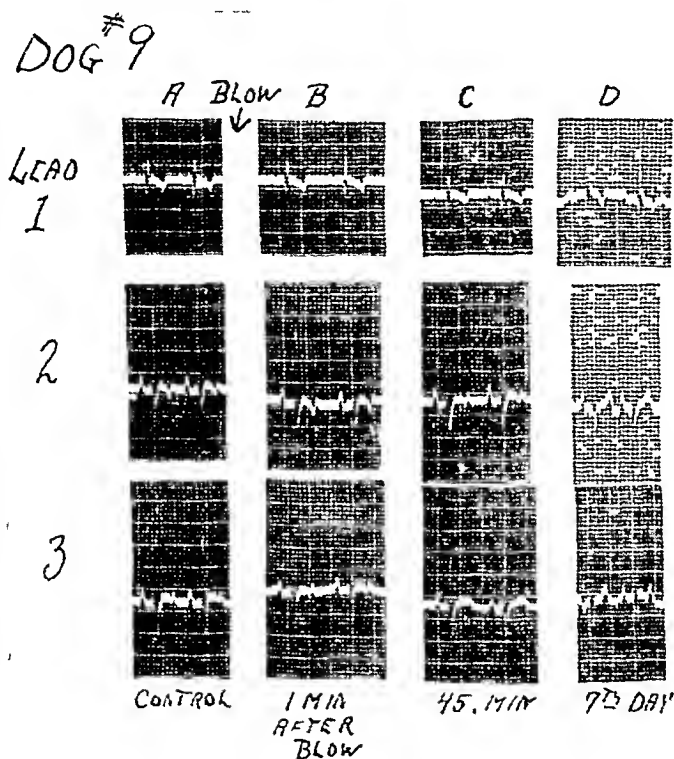

FIG 12 Dog 9

cardiogram *A* was taken Then while electrocardiogram *B* was being taken one hard blow was struck with a 10 pound hammer to the left chest of the animal Following this (figure 22) electrocardiogram *C* was taken in one minute, *D* in four minutes, *E* in five minutes, *F* in eight minutes, and *G* in 11 minutes at which time the dog died An autopsy was performed which revealed hemorrhage into the anterior and posterior mediastinal spaces, hemorrhage into the tissue about the great vessels, also small areas of contusion and hemorrhage into the myocardium of the anterior wall of the right and left auricles There was a small amount of free blood in the pericardial sac Microscopic examination revealed a small amount of hemorrhage under the visceral pericardium of the right and left auricular myocardium

Dog 14 (figure 23) A German Shepherd dog, weight 70 pounds, was given 1.5 gm of sodium amytal intraperitoneally, and one hour later control electrocardiogram *A* was taken, following which the right and left vagus nerves and the superior and middle cervical ganglions were cut on both sides, and the spinal cord severed between the third and fourth cervical vertebrae, and after this was accomplished the

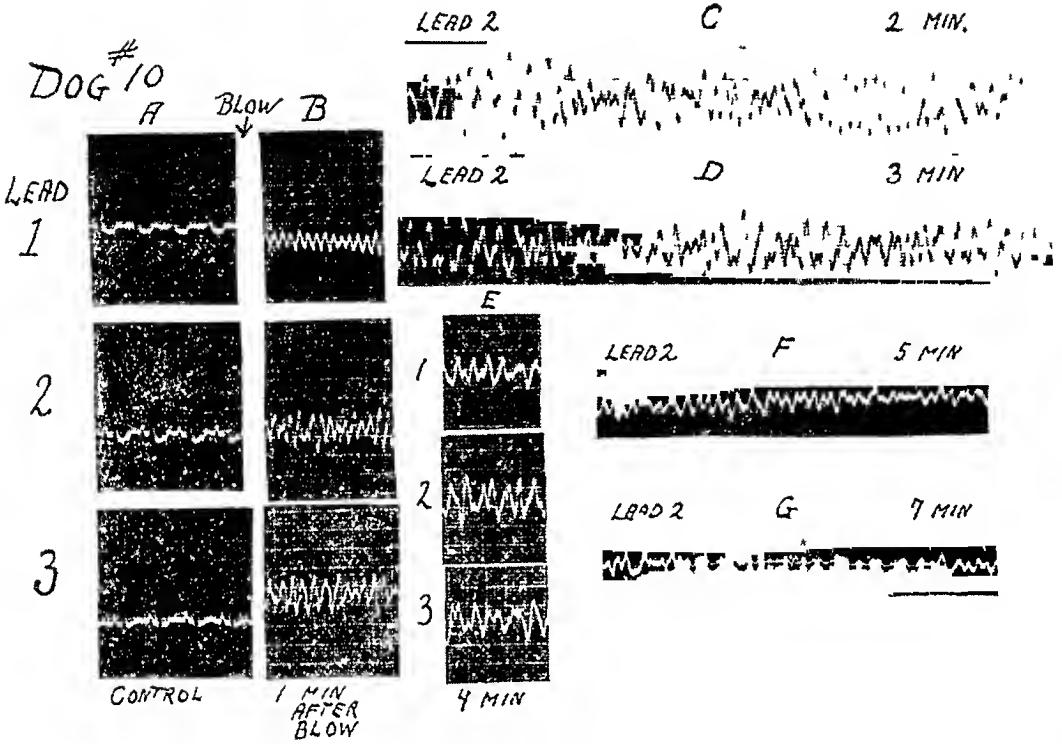

FIG 13 Dog 10

FIG 14 Dog 10

control electrocardiogram *B* was taken While electrocardiogram *C* was being taken a hard blow was struck with a five pound hammer directly to the left chest at the point of maximum intensity of the apex beat Five minutes later while electrocardiogram *D* was being taken the same type of blow was again delivered, and the same procedure repeated in five more minutes while electrocardiogram *D* was being

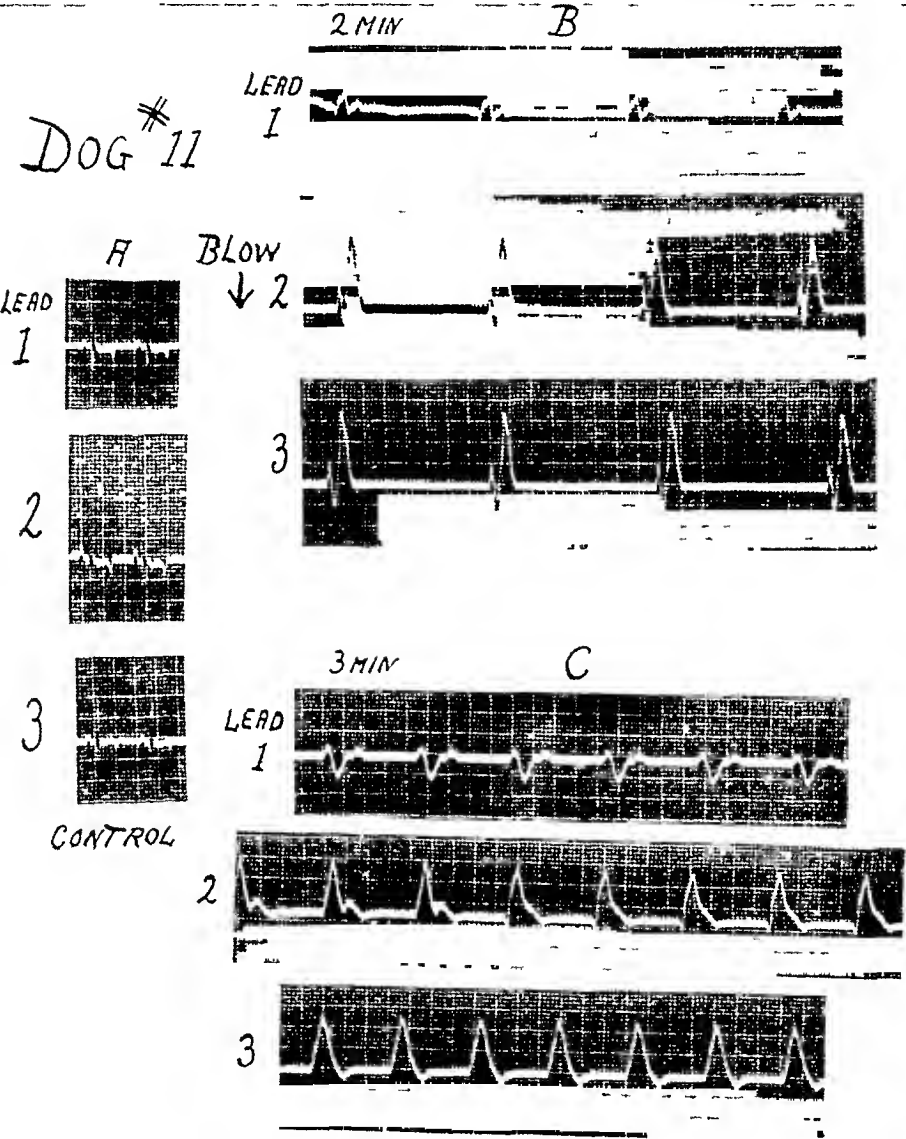

FIG 15 Dog 11

taken Thirty-one seconds after electrocardiogram *D* the electrocardiogram *F* (figure 24) was taken, and five minutes after the previous blow another similar one was delivered while electrocardiogram *G* was being taken followed in one minute by electrocardiogram *H* Five minutes after the previous blow another similar blow was delivered while electrocardiogram *I* was being taken Five minutes later this procedure was repeated while electrocardiogram *J* (figure 25) was being taken

Three seconds later electrocardiogram *K* was taken, two minutes *L*, four minutes *M*, and six minutes later electrocardiogram *N*. Five minutes after this last electrocardiogram another similar blow was struck while the electrocardiogram *O* (figure 26) was being taken, and one minute later electrocardiogram *P* was taken. After a five minute interval another similar blow was struck while electrocardiogram *Q* was being taken and the tracings *R* and *S* (figure 27) are continuous with the previous electrocardiogram. *T* was taken three seconds later and *U* 42 seconds after this. Five minutes after this last electrocardiogram another blow of the same type

FIG 16 Dog 11

was delivered while electrocardiogram *V* was being taken, and the procedure repeated in five more minutes while electrocardiogram *X* (figure 28) was being taken. Electrocardiogram *W* was continuous, and then again the blow was repeated, while electrocardiogram *Y* was being taken. At this time the dog was killed by chloroform and an autopsy performed which showed that the right and left vagus nerves had been cut, as well as the superior and middle cervical ganglions on both sides and the spinal cord. There was a small amount of ecchymosis into the intercostal muscles of the third and fourth left interspaces just to the left of the sternal margin, and the second and third ribs on the right were fractured without displacement at the costochondral junction. Corresponding to these external injuries were small areas of ecchymosis in the pleura. There was a moderate amount of hemorrhage in the extreme apical portion of both lungs. The pericardial sac contained about two ounces of clear fluid and on the anterior visceral pericardium near the apex was a small roughened opaque area two cm in diameter, while just to the left of this was a

H 14 MIN LEAD 2

I 21 MIN LEAD 2

FIG 17 Dog 11

DOG #12

FIG 18 Dog 12

small area of hemorrhage and muscle contusion. There was a small rupture 6 mm in length between the anterior cusp and the right posterior cusp of the aortic valve with moderate hemorrhagic infiltration about the base of this valve but no invasion of the myocardium. Microscopic examination revealed the hemorrhages of the anterior wall and the septal portion of the left ventricle to be limited to the subendothelial tissue and not to invade the myocardium. Sections taken through the area of pericardial thickening on the anterior surface of the left ventricle revealed an old pericardial scar consisting of fibrous tissue which in some areas was piled up in a villus like manner. The lungs showed extensive hemorrhagic infiltration of the interstitial tissue and the alveoli and a moderate amount of atelectasis.

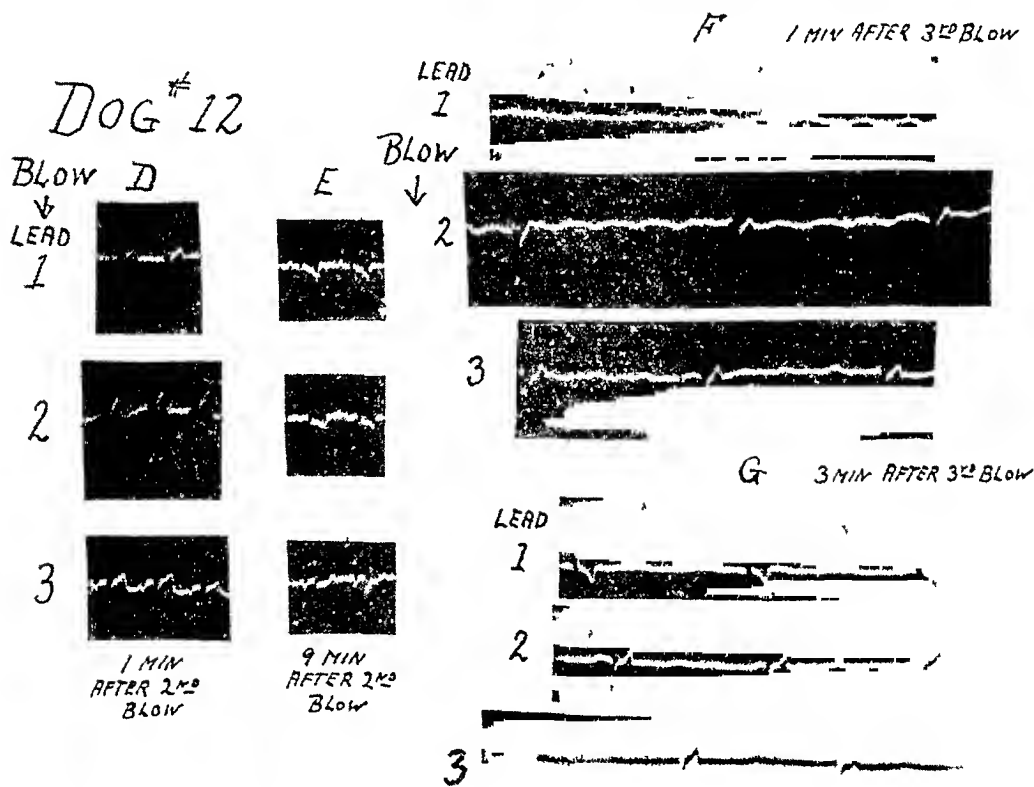

FIG 19 Dog 12

Dog 15 (figure 29) A mongrel English setter, weight 35 pounds, was given 0.75 gm of sodium amytal intraperitoneally, and one hour later the control electrocardiogram *A* was taken. At this time both vagus nerves, the superior and middle cervical ganglions on both sides, and the spinal cord between the third and fourth cervical vertebrae were cut. Following this control electrocardiogram *B* was taken, and then while electrocardiogram *C* was being taken a hard blow was struck with a five pound hammer to the area of maximum intensity of the apex beat on the left chest wall, one minute later electrocardiogram *D* was taken. Then five minutes after this electrocardiogram another similar blow was delivered while the electrocardiogram *E* was being taken, and one minute later electrocardiogram *F* was taken. After a five-minute interval another similar blow was struck while electrocardiogram *G*

(figure 30) was being taken, and again the procedure was repeated after a five-minute interval while electrocardiogram *H* was being taken and electrocardiogram *I* starts 62% seconds after *H*, and is continued on electrocardiogram *J* (figure 31). The electrocardiograms follow each other after various time intervals, *K* after 15% seconds, *L* one minute later, *M* (figure 32) 13% seconds later, *N* two minutes later, *O* three minutes later, *P* two minutes later, and *Q* two and one-half minutes later, at which time the dog died. An autopsy showed that the right and left vagus nerves

FIG 20 Dog 12

had been cut as well as the superior and middle cervical ganglions on both sides and the spinal cord. There was a small rent two inches long through the intercostal muscle of the left fourth intercostal space about two inches from the sternal margin with slight ecchymosis of the surrounding muscle tissue, but there were no fractures of the ribs or sternum. There was a massive collapse of both lungs with a small amount of bloody fluid into the pleural cavities. There were two tears about one cm in length in the endocardium of the auricles, one close to the superior vena cava and the other just above the mitral valve. There was also a small rent in the superior surface of the liver. Microscopic examination revealed some atelectasis and moderate hemorrhagic infiltration of the lungs. Sections of the tears in the auricles showed a superficial absence of the endocardium which was replaced by fresh hemorrhage infiltrated slightly into the underlying muscle tissue.

GENERAL REMARKS

All electrocardiograms were taken in Leads I, II and III unless otherwise stated, and all leads were standardized at the time of each electrocardiogram. The electrodes used were of the ordinary small metal type, and the position of the animal remained the same throughout each experiment, but

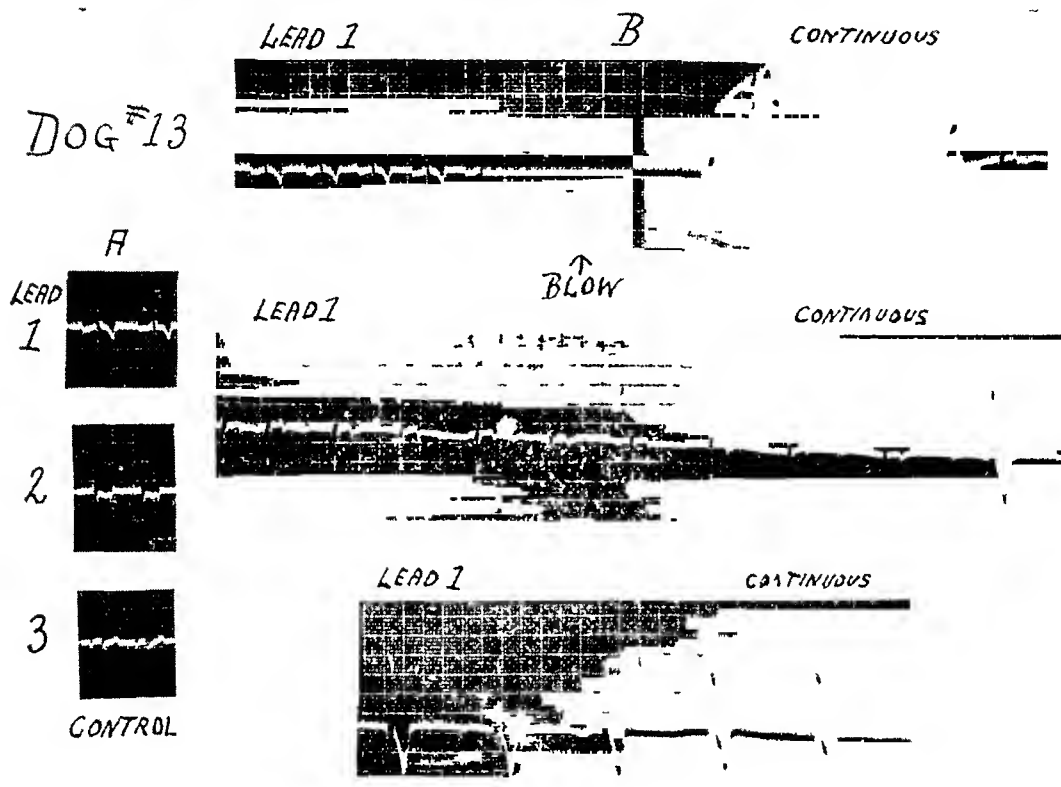

FIG 21 Dog 13

the animals that were allowed to recover from the anesthesia and live were taught to stand still while the electrocardiograms were taken. Many microscopic sections were studied on each animal from the pericardium, walls of the great vessels, myocardium, coronary vessels, cusps of the valves, conduction system and lungs.

ELECTROCARDIOGRAPHIC RESULTS

Dog 1 (figure 1) Five minutes after a moderate blow there was an increase in the T_1 negativity (ekg B) from the control and the T_3 became positive. There was no further change until five and one-half hours after a second blow when the T_1 and T_2 became deeply inverted and the T_3 upright and pointed, with variation in the RS-T component (ekg G).

Dog 2 (figure 2) The first series of moderate blows did not produce

FIG 22 Dog 13

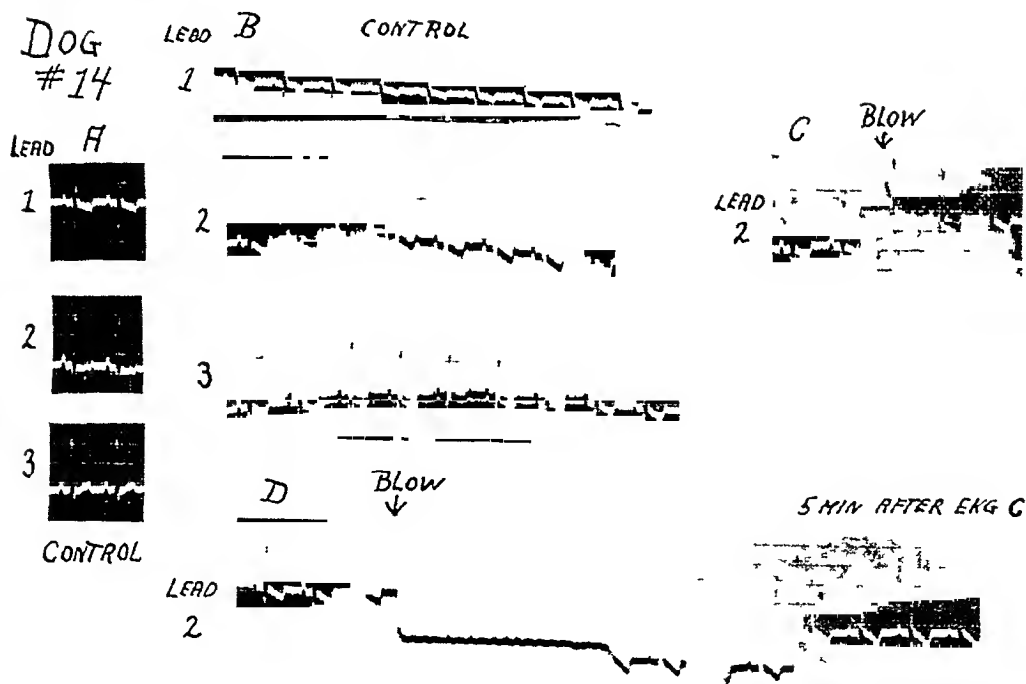

FIG 23 Dog 14

any marked deviation in the electrocardiogram from the control but five and three-fourths hours later and 45 minutes after the second series of blows the T_1 and T_2 changed to positive and the Q_1 disappeared (ekg *H*)

Dog 3 (figure 3) Five minutes after the first blow (ekg *B*) the T_3 became negative and the downward deflection of the QRS_3 in the control disappeared and became upright. These changes were not influenced by the following series of blows

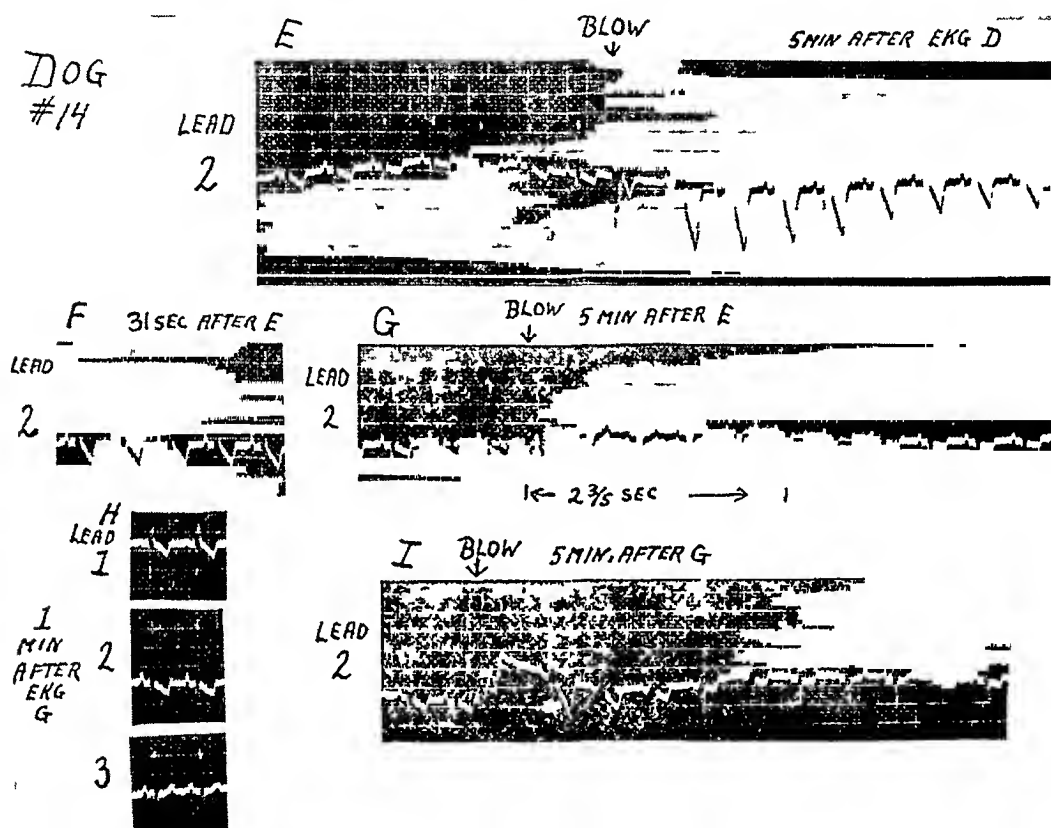

FIG 24 Dog 14

Dog 4 (figure 4) Five minutes following a heavy blow (ekg *B*) there was a change from the control to a negative T_1 , T_2 and T_3 , and one and one-half hours later (ekg *D*, Lead II) and two and one-half hours later (ekg *E*, Lead III) transient sino-aortic block appeared

Dog 5 (figure 5) Twelve seconds after a hard blow there was a change from the control in the RS-T component and (figure 5, ekg *B*) the T_1 became negative while the T_3 changed to positive, but later returned to negative as in the control. One and one-half hours later another hard blow was struck and within 10 seconds (figure 7, ekg *G*) interventricular block developed in Leads I and II with rapid decrease in the greatest deflection on the QRS wave and return to normal rhythm in Lead III. The

negative T_1 which occurred immediately following the first blow became more marked and was still present (figure 8, ekg *K*) two and one-half hours after the second blow

Dog 6 (figure 9) After four series of heavy blows there were no marked electrocardiographic changes.

Dog 7 (figure 10) After a heavy blow was delivered there were no marked electrocardiographic changes until the eighth day when the T_1 be-

FIG 25 Dog 14

came positive (ekg *E*) and returned to negative on the fortieth day (ekg *F*) and at this time what appeared to be ventricular extrasystoles were seen by the string shadow but were not caught by the camera. The T-wave became positive in Lead II on the hundredth day (ekg *H*). There was also marked deviation of the RS-T component in the electrocardiograms taken after the eighth day (ekg *E, F, G, H*), and on the hundredth day (ekg *H*) no P-wave was seen in Leads II and III and in Lead I there appears to be a diphasic P-wave with a P-R interval of 0.24 second.

Dog 8 (figure 11) One minute after a hard blow (ekg *B*) there was a change from the control to a positive T_2 and T_3 but this was transient and on the second day (ekg *E*) the electrocardiogram was similar to the control.

Dog 9 (figure 12) There were no marked changes from the control.

in the electrocardiograms taken following the blow until the seventh day (ekg *D*) when the T_2 and T_3 were positive

Dog 10 (figure 13) One minute after the blow the electrocardiogram *B* revealed ventricular fibrillation which ended in death 16 minutes later (figure 14, ekg *M*)

Dog 11 (figure 15) Two minutes after the blow (ekg *B*) there is an absence of the P-wave, evidently an auricular paralysis with an idio-ventricular rhythm Three minutes after the blow (ekg *C*) there is an idio-

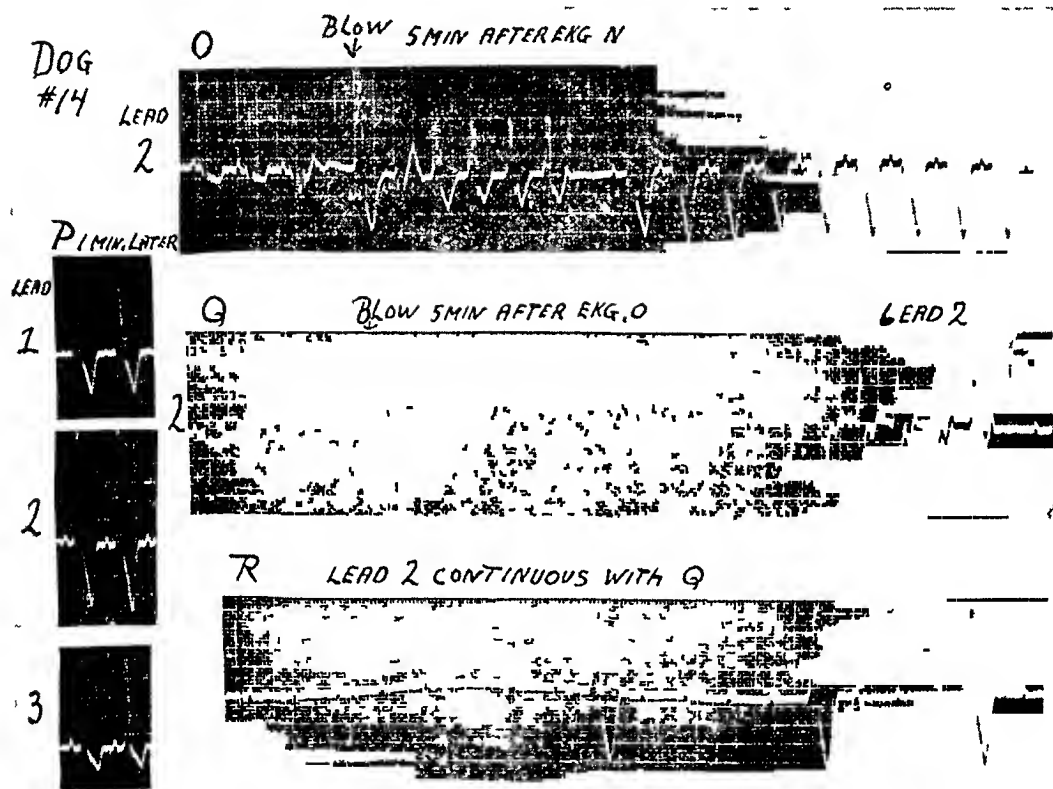

FIG 26 Dog 14

ventricular rhythm and in Lead I the P-wave appears following the QRS wave, and also in the first part of Lead II, and in the fourth complex the P-wave begins to be gradually incorporated in the QRS wave until the P-wave has completely disappeared and permanent auricular paralysis established with monophasic ventricular complexes of the dying heart (figure 16, ekg *D*, *E*) Death occurred 21 minutes after the blow (figure 17, ekg *I*)

Dog 12 (figure 18) One minute after a blow the electrocardiogram changed from the control to (ekg *B*) an interventricular block, which in Lead I is shown to be transient and suddenly in the third complex the QRS wave greatly decreases in magnitude and the T-wave becomes inverted until in four minutes the complexes in all leads (ekg *C*) have returned to

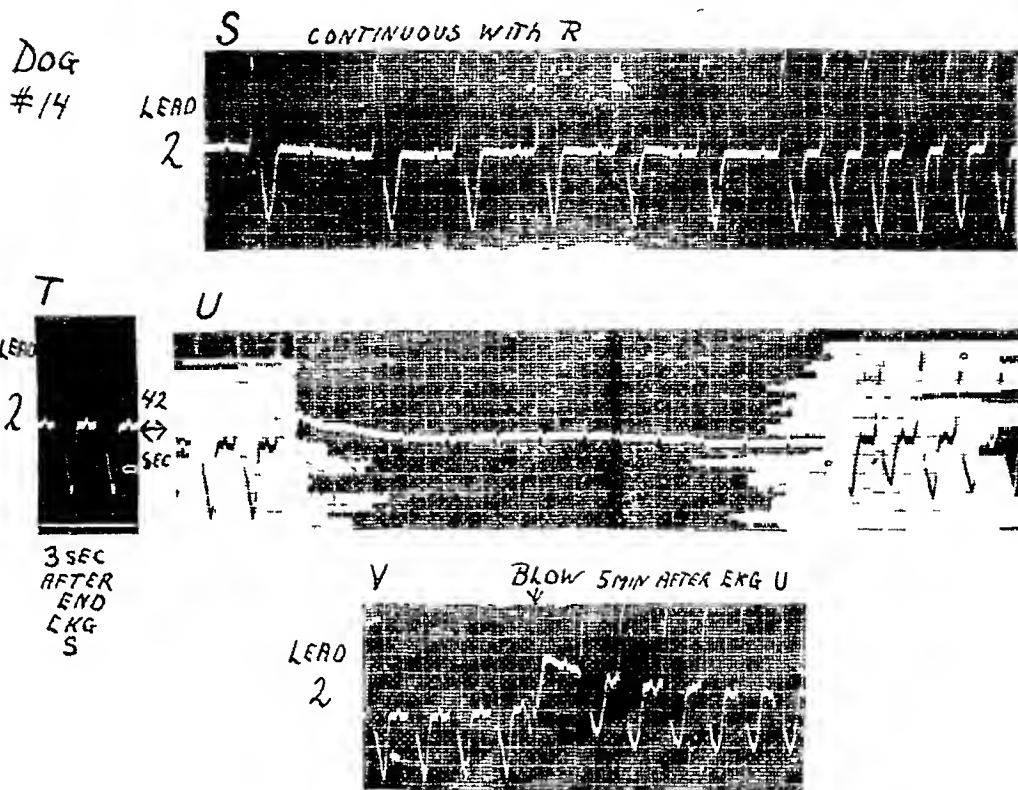

FIG 27 Dog 14

FIG 28 Dog 14

the type seen in the control (ekg *A*) Another blow was struck and again within one minute (figure 19, ekg *D*) interventricular block occurred and in nine minutes returned to the normal rhythm (ekg *E*) seen in the control Another blow was struck and one minute later (ekg *F*) an idio-ventricular rhythm was established with an absence of the P-wave, with slow undulating waves of the base line Three minutes after the blow (ekg *G*) the idio-ventricular rhythm was still present with some changes in the character of the QRS waves and the appearance of a negative pointed T₁ wave Thir-

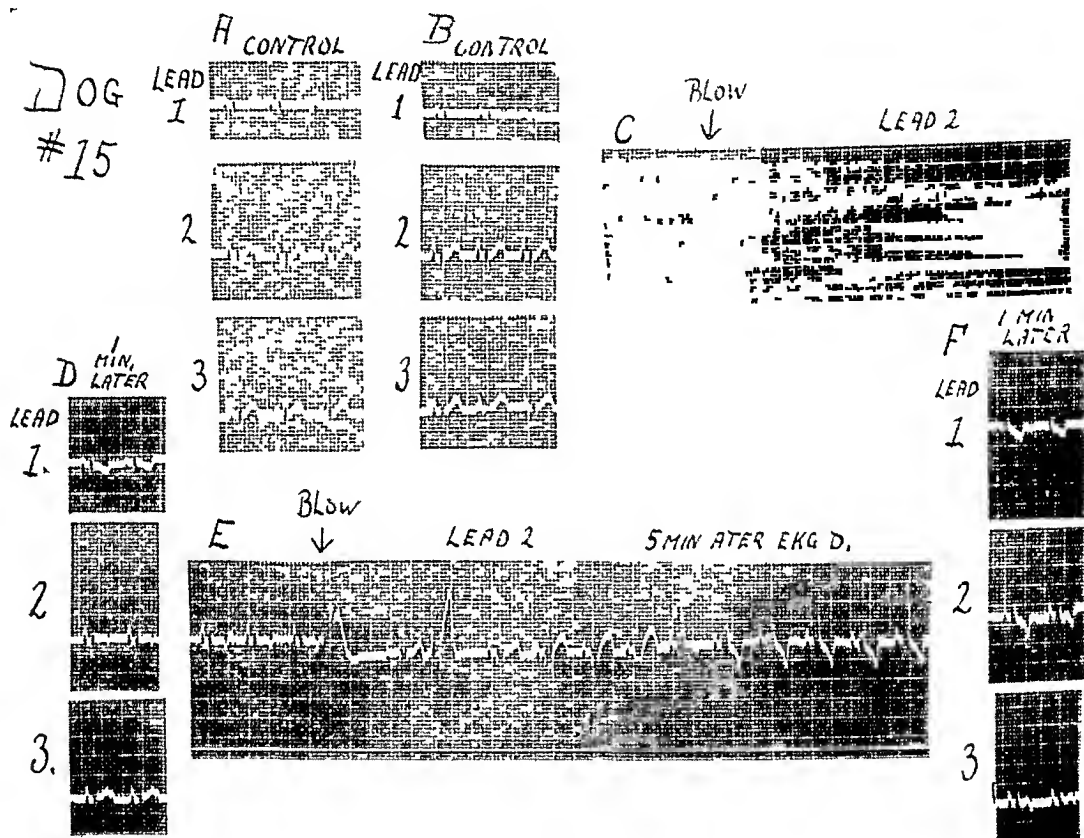

FIG 29 Dog 15

teen minutes after this blow (figure 20, ekg *H*) there was a return to the normal rhythm of the control and sino-auricular block in Lead I One minute after another blow (ekg *I*) idio-ventricular rhythm appeared with no P-waves and slow rhythmic undulations of the base line and after four minutes there was (ekg *J*) auricular paralysis with monophasic ventricular complexes and death at this time

Dog 13 (figure 21) While Lead I of the electrocardiogram was being taken (ekg *B*) a blow was delivered with the string protected and in 4.2 seconds interventricular block with gradual slowing of the rate until, in 12.6 seconds all signs of a P-wave disappeared with an idio-ventricular

hythm One minute after the blow (figure 22, ekg C) the rhythm was the same but the ventricular complexes changed in character and after four minutes (ekg D) there was a complete heart block with idio-ventricular rhythm, an occasional ventricular extrasystole, and pairs of rhythmic P-waves separated by long intervals of auricular paralysis and idio-ventricular rhythm with diphasic ventricular complexes until death in eleven minutes (ekg E, F, G)

FIG 30 Dog 15

Dog 14 (figure 23) Two blows were delivered while Lead II of the electrocardiogram was being recorded (ekg C, D) without marked changes. The blow was repeated (figure 24, ekg E) in the same manner and in 0.6 second and with the next complex, interventricular block occurred which was transient and (ekg E, F) returned to the normal rhythm (ekg G) of the controls in five minutes. At this time another blow was struck while Lead II of the electrocardiogram was being taken (ekg G). The next beat after the blow revealed a change to an upright T-wave, change in the RS-T component and the Q-wave of the QRS complex disappeared and the initial deflection of the ventricular complex became upright. These changes were transient and within 2.6 seconds the QRS wave returned to the former character and the T-wave became negative. One minute later (ekg H)

there was a return to the normal rhythm of the controls Five minutes later (ekg *I*) the blow was repeated while Lead II of the electrocardiogram was being taken and the next complex revealed a transient interventricular block with return to the control rhythm in three seconds Five minutes later another blow was struck (figure 25, ekg *J*) while Lead II of the electrocardiogram was being taken and after 0.8 second of cardiac standstill interventricular block developed, with an occasional ventricular extrasystole (ekg *K*), which was transient (ekg *K, L, M, N*) and returned to the nor-

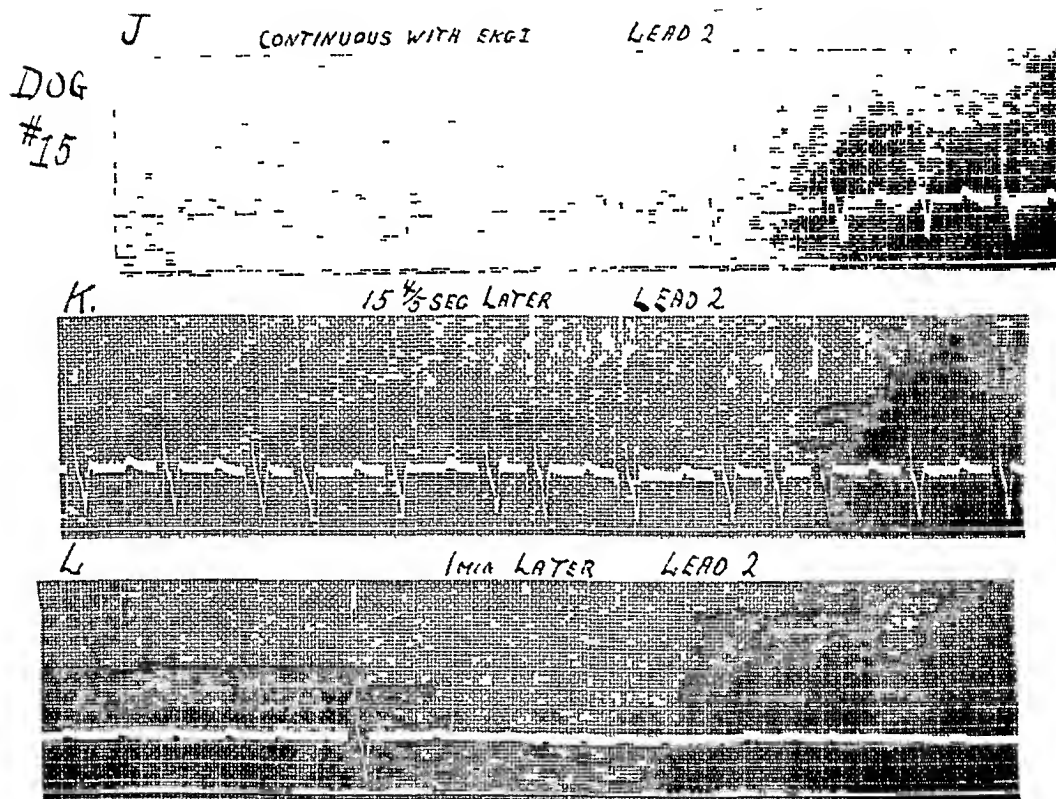

FIG 31 Dog 15

mal control rhythm (figure 26, ekg *O*) 11 minutes after the blow, at which time the blow was repeated under like circumstances (ekg *O*). Immediately ventricular tachycardia developed and in 2.2 seconds a P-wave appeared with interventricular block (ekg *P*). Then after another five-minute interval another similar blow was struck (ekg *Q*) which was followed by 0.8 second of cardiac standstill, then by ventricular tachycardia with various types of diphasic ventricular complexes, and after 6.8 seconds a P-wave appeared with a complete heart block and only occasional idioventricular complex (ekg *Q, R*) which became more frequent until, after six seconds (figure 27, ekg *S*) there is 2 to 1 block and in seven seconds interventricular block, changing in 10.4 seconds to ventricular tachycardia,

then back to interventricular block (ekg *T*) About 42 seconds later there was complete heart block with ventricular standstill followed by interventricular block again (ekg *U*) Five minutes later another blow was delivered while (ekg *V*) the interventricular block was present without marked changes Five minutes later when this was repeated (figure 28, ekg *X*) the interventricular block disappeared and ventricular tachycardia occurred for five complexes, after which there was a return to interventricular block, with occasional changing back and forth between these rhythms (ekg *W*, *Y*)

Dog 15 (figure 29) A blow was delivered while Lead II of the electrocardiogram was being taken (ekg *C*), which was followed by one ventricular extrasystole with immediate return to the normal control rhythm (ekg *C*, *D*) This was repeated five minutes later with transient interventricular block of the right and left branches of the Bundle of His and one ventricular extrasystole, each change being separated from the other by a normal complex (ekg *E*) and in one minute the rhythm of the control returned (ekg *F*) After another five-minute interval a similar blow was given and again (figure 30, ekg *G*) transient interventricular block immediately developed to return to the normal control rhythm in five minutes when the final blow was delivered, followed by complete heart block and ventricular standstill for 73 seconds (ekg *H*, *I*) after which 5 to 1, 4 to 1, 3 to 1, and 2 to 1 block occurred (figure 31, ekg *J*) The idio-ventricular complexes appear in groups of two's and three's and one minute later the P-waves became very small in amplitude (ekg *L*), finally disappearing with one last diphasic idio-ventricular complex, then death

DISCUSSION AND COMMENT

The most frequent electrocardiographic changes were in the T-waves and the RS-T components and occurred in 10 of the dogs* In the first series of experiments with Dogs 1, 2, 3, 4 and 5, these changes occurred during a period varying from a few minutes to a few hours, after various degrees and types of chest injuries Since all the electrocardiograms were taken with the dogs in the same position, the chance of error was removed Only two of these five dogs showed abnormal lesions of the heart, Dog 1 with hemorrhage into the mediastinal space and cusps of the pulmonic and mitral valves and Dog 5 with thickening and hemorrhage into the pericardium and into the tissue about the base of the heart While three of the dogs had hemorrhage into the lung, two others with more marked T-wave and RS-T component changes did not show this lesion and therefore these changes were not attributed to generalized anoxemia, neither can they be attributed to increase of the fluid in the pericardial sac because in none of the five dogs was this found to be present The gross and microscopic examina-

* Since this article has been written additional experiments of the same type have been performed and in one dog, we were able to produce auricular fibrillation following external trauma to the chest

tion of the hearts of these dogs revealed them to be normal except for slight hemorrhage into the valve cusps of Dog 1. In Dog 4 there were no abnormal lesions found.

The second series, Dogs 6, 7, 8 and 9, were not killed following the external chest injury. Dog 6 lived a few hours, then died from hemorrhage into both lungs. The autopsy revealed a rupture of the diaphragm and a tear in the pericardium with a small amount of hemorrhage into the pericardial sac, but there were no electrocardiographic changes observed.

Dog 7 was disregarded because following sudden death, upon the one hundred and twenty-first day, there was found some thickening of the coronary artery which was not traumatic but could possibly have caused electrocardiographic changes.

Dog 8 showed immediate T-wave and RS-T component changes, as did also Dog 9 on the seventh day. Dog 8 died on the third day and the autopsy revealed a small tear in the pericardium. Dog 9 died on the sixteenth day and the autopsy revealed congestion of the lungs and heart failure cells. Evidently in Dog 9 heart failure had been present before death, although in neither case were any abnormal lesions found in the myocardium, and it is possible that this failure may have been due to some serious type of arrhythmia which was not present at the time the electrocardiograms were taken.

The third series, Dogs 10, 11, 12 and 13, were struck heavy blows to the chest in an attempt to produce death in as short a time as possible. In Dog 10 ventricular fibrillation was produced with death in sixteen minutes, in Dog 11 idio-ventricular rhythm with auricular paralysis occurred with death in 21 minutes. The autopsies failed to reveal any abnormal lesions. Dog 13 had immediate changes in the T and QRS waves and the RS-T component and later developed a heart block, interventricular block, and finally auricular paralysis with idio-ventricular rhythm which eventually caused death. The autopsy in this case revealed hemorrhage into the tissue about the base of the heart, into the pericardial sac with slight sub-pericardial and myocardial hemorrhage of the wall of the right and left auricles. These three dogs in the third series died as a result of fatal arrhythmias and demonstrated the possibilities of sudden death from external chest injuries with insufficient pathology to explain these arrhythmias or to be considered as a cause of death. Dogs 12, 14 and 15 demonstrated that many various types of arrhythmias occur immediately and in a very short time return to normal rhythm but with each successive chest injury the arrhythmia remained for an increasing period.

In the fourth series, Dogs 14 and 15, the right and left vagus nerves, the right and left superior and middle cervical ganglions and the spinal cord were cut before any of the blows were delivered. This was done to avoid the possibility of extra-cardiac lesions producing the electrocardiographic changes. Although the first two hard blows struck Dog 14 did not pro-

duce electrocardiographic changes, almost all the arrhythmias, T-wave and RS-T component changes seen in the other dogs were reproduced in these two animals. Similar traumatic lesions outside the heart, such as contusion and hemorrhage of the lungs, rupture of the liver and diaphragm, were produced in these dogs which would seem to indicate that the changes seen in the dogs of the other series were not due to injury outside the heart.

Considering the entire 15 animals the most frequent lesion produced was injury of some type to the lung. This occurred in eight dogs, following both severe and mild blows to the chest. Rupture of the liver occurred twice, and rupture of the diaphragm once. These lesions, together with hemorrhage into the mediastinal space, were the chief lesions found outside the heart. The most frequent cardiac lesions were sub-endocardial and sub-pericardial hemorrhage which occurred four times, as did also pericardial injury and tear with or without free blood in the pericardial sac. With the exception of hemorrhage into the valve cusps, which occurred twice, and hemorrhage into the tissue about the base of the heart, no other lesions were found. In three dogs there were no lesions of any kind and, since the electrocardiographic changes are sudden and transient, these changes may be considered due to edema of the myocardium and the various parts of the conduction system. These changes are also similar to those following experimental coronary artery occlusion and injury to the Bundle of His, in dogs. It is evident that mild and severe blows produce various types and degrees of electrocardiographic changes and the tendency is for the heart to return to normal within a very short time. On the other hand the same degree of blow may produce a fatal arrhythmia. It is also evident that there need be no injury to the chest wall, which occurred only in the two dogs of the last series, to produce both electrocardiographic changes and abnormal lesions of a serious nature.

ADRENAL CORTICAL TUMOR, A REPORT OF FOUR CASES *

By CHARLES H. LAWRENCE, M D , F A C P , *Boston, Massachusetts*

IN his paper on tumors of the suprarenal cortex read before the Staff of the Mayo Clinic in 1933, Kepler¹ cites the following quotation from Rowntree and Ball

"We may say that there are various types of tumors of the suprarenal gland, resulting in a large variety of clinical symptoms and syndromes, many of which are difficult to explain adequately in the present state of knowledge. Correlated clinical, pathological and chemical studies are urgently needed." The following four case reports, which more or less imperfectly meet these specifications, seem worth adding to the literature

Case 1 F R , female, 13 yrs 10 mos , first seen November 1, 1928

Family History Father, mother, two sisters living and well. No family history of endocrine disease. Mother's catamenia irregular and profuse. One sister hypomenorrheic through adolescence, normal since.

Past History Measles, mumps, chicken pox, pertussis in childhood. Tonsillectomy in childhood. Appendectomy at 11 for acute appendicitis.

Present Illness Menarche at 10 yrs 8 months. During the next nine months menstruation was regular every 28 days, lasted four to five days, amount regarded as normal, no pain. In June 1926, patient menstruated normally but had not menstruated since, an interval of 17 months. During the first six months of amenorrhea there was no change in her general condition, and little attention was paid to the lack of menstruation.

In June 1927, patient's mother noted beginning masculinization. The voice became deeper and hoarser, and coarse dark hair appeared on arms, legs, abdomen, cheeks and chin. Both voice change and hair growth increased steadily. The patient's general health remained excellent. She denied any other symptoms than those enumerated.

Physical examination showed a well developed and nourished girl. The body contour was normally feminine. There was moderate acne of the face, chest and back. There was moderate hypertrichosis of cheeks, chin, and upper lip, and a considerable growth of coarse, dark hair on the arms and legs. The pubic hair extended upward to the navel. The labia were slightly hypoplastic, the clitoris was slightly larger than normal. Rectal examination disclosed a rather small uterus, but no other pelvic abnormality. Abdominal examination revealed no abnormality. The physical findings were otherwise normal.

Laboratory Findings The urine was normal as was the blood morphology, and chemistry. Renal function (phenolsulphonephthalein elimination) was 59 per cent in two hours. Basal metabolism was plus 3 per cent, with normal pulse rate, blood pressure and temperature. Roentgen-rays of the skull, kidneys and urinary tract showed no pathology. Eye grounds and visual fields were normal. Pelvic ex-

* Received for publication July 28, 1937

From the Endocrine Clinic of the Boston Dispensary

amination with anesthesia showed no abnormality other than slight uterine hypoplasia

Course The sudden cessation of previously normal menstruation, and the masculinization suggested either tumor of the adrenal cortex, pineal tumor, or tumor of the ovary (Basophilic adenoma of the pituitary was unknown at that time) No diagnosis could be definitely established, however, and the patient was kept under observation for a year During this period no change occurred in the clinical picture there was no loss of weight, and the blood pressure, observed repeatedly, remained perfectly normal Injections of "Amniotin" and "Estrogen" were without demonstrable effect

At the end of a year, the patient was seen in consultation by Dr D L Jackson, who confirmed the physical findings already noted In his opinion, sclerosis of the ovarian cortices was the most probable diagnosis, and at the request of the patient, an exploratory operation was performed, December 5, 1929

Operative Findings The cervix was small Curetting the uterus yielded no endometrium, in spite of the fact that a serrated curet was used On opening the abdomen, the uterus was found to be small and retroverted The Fallopian tubes were normal The ovaries were smooth with thickened cortices Both ovaries were split, and were found packed with small cysts, which were evacuated The cortex was then peeled The left kidney and adrenal body were normal to palpation There was a question as to whether the right adrenal gland could be felt, but no pathological condition could be demonstrated The wound was therefore closed Pathological report on the curettings No endometrial tissue found Specimen from ovary—simple cyst, and numerous unripe follicles

The patient made an uneventful recovery There was no change in the clinical picture She was seen at intervals of three to six months during the next six years, but no significant development occurred until September 1934 (nearly five years after operation), when she began to develop moderate dyspnea and palpitation on vigorous effort Examination at that time showed the heart to be normal, but the resting pulse rate had increased to 96 per minute, and the blood pressure had risen to 140 systolic and 80 diastolic The retinal arteries were slightly narrow, the veins moderately over full Blood and urine were normal The breasts had become atrophic, and there was marked hair growth around the areolae Abdominal examination was negative Intravenous pyelograms showed that the right kidney was larger than the left, and its border was somewhat irregular The pelves, infundibulae and calices filled well, but the upper calix of the right kidney was depressed There were no other abnormal findings Neither Dr Prather nor Dr Morrison who together conducted the examination, felt that there was enough evidence of adrenal tumor to justify operation They advised further observation

In April 1935, the patient's condition was essentially unchanged, the slight hypertension persisted, and abdominal palpation gave a sense of an indefinite mass in the right flank not apparently connected with the liver Repetition of the pyelogram showed, on the right side, numerous small areas of calcification scattered between the levels of the first lumbar vertebra and the tenth rib posteriorly, and a suggestion of the rounded outline of a mass overlying the upper pole of the right kidney

On the basis of these findings, the diagnosis of tumor of the right adrenal gland seemed established, and after consultation with Dr Prather, it was decided to operate after preliminary radiotherapy had been completed There was no significant change in the patient's condition up to the time of operation, July 25, 1935 At operation, a rounded, encapsulated tumor on the right adrenal 12.5 by 10 by 8 cm was removed It was completely encapsulated, fairly homogeneous, brown, opaque and soft Scattered through it, particularly near the periphery, were bony spicules Because of the size of the tumor it was necessary to remove both the right kidney and

the right adrenal gland with it. The latter showed a slight thickening of the cortex, and was otherwise normal. The kidney was normal.

The patient showed a fall in blood pressure to 100 systolic and 70 diastolic, 24 hours after operation. Eschatin was administered during the next three days, and gave a prompt response. Thereafter, the blood pressure varied between 120 and 130 mm systolic with a diastolic of 80 mm. The patient made an uneventful recovery.

Within three weeks after operation her voice showed a definite return to the feminine timbre and within two months was completely restored to its former quality. The patient began to menstruate on September 1, and flowed four days normally, without pain. Thereafter she has continued to menstruate normally and regularly. One year after operation examination showed some gain in weight and marked regression of the hypertrichosis. A recent report states that the abnormal hair growth has now practically disappeared.

COMMENT

The outstanding feature of this case is the long duration of the syndrome before its cause could be identified. In November 1928, the masculinization was sufficiently impressive to leave no doubt that there was serious disturbance of endocrine function, but a rather complete diagnostic study afforded no evidence sufficient to identify the gland at fault. Such evidence as there was suggested pathology of the adrenal cortex or ovary rather than of the pituitary, possibly because Cushing's paper² had not yet appeared to emphasize the similarity of the clinical pictures produced by pituitary basophilism and tumors of the adrenal cortex. In retrospect, a number of features characteristic of pituitary basophilism are lacking in this case. There was no "rapidly acquired, peculiarly disposed and usually painful adiposity," no kyphosis, no "plethoric appearance of the skin with purplish lineae atrophicae," no vascular hypertension for six years after the clinical picture was fully established, no erythremia, and no backache or fatigability. The patient's health, as that term is usually understood, was excellent at all times, and she attended school and college during the years that she was under observation, taking part in all the usual activities.

The absence of all these characteristic symptoms is worth remarking, since some or all of them were present in the other patients described in this report. Why they should have been lacking in this patient cannot be explained, nor is speculation profitable. Another feature worth emphasizing is the definite masculinization of the voice, and its return to normal after removal of the tumor. This feature is not mentioned by Cushing as characteristic of pituitary basophilism,² and although it is not always present in the adrenocortical syndrome, it should be of considerable diagnostic value when it exists.

The third feature which justifies comment is the evidence afforded by the exploratory operation performed one year after masculinization had become well established. Unquestionably the tumor of the right adrenal cortex was present at that time, but it could not be palpated through the abdominal incision. It must be concluded that it was very small at that time (though the difficulty of palpating the adrenals through a median ab-

dominal incision is considerable) and therefore that even very small tumors of the cortex are capable of causing marked masculinization. The condition of the ovaries is also interesting in view of the rapid reestablishment of normal menstruation following the second operation. At the first laparotomy they were found to be sclerosed and cystic, and were subjected to a considerable degree of surgical trauma, yet they promptly reassumed their normal function six years later when the inhibiting tumor was removed. It is, therefore, obvious that the organic pathologic changes discovered at the first operation were not the primary cause of the amenorrhea.

Case 2 A married woman, 24 years old, entered the hospital March 9, 1936, in coma.

Family History Father, mother, and four siblings were living and well. The maternal grandmother was allergic.

Past History No serious illnesses, no operations. As an infant, the patient was allergic to eggs, and in recent years to grass pollens, the symptoms being controlled by desensitization treatment.

Menstruation began during her fifteenth or sixteenth years, and was regular and normal until 1933, when she developed functional menorrhagia. At that time she showed a moderate secondary anemia, a basal metabolic rate of minus 21 per cent, normal blood sugar, a rather flat sugar tolerance curve. Physical examination showed slight symmetrical enlargement of the thyroid, hyperplastic breasts, and a small uterus. Three months' treatment with Antuitrin S, 200 R U every other day during the intermenstrual intervals, restored menstruation to normal, and it remained so until the present illness. The patient's health had been good until a week before entering the hospital, though her parents thought she seemed more tired than usual for several months before its onset.

Present Illness February 29, 1936, while driving her car she had a brief attack of blurred vision and felt rather faint. She was, however, able to drive her car home, and after luncheon and a short rest, felt as well as usual. The next day she woke at seven, went to her sister's room for a time, and then returned to her bed for another nap. At noon her mother found her still "asleep," perspiring profusely. She was roused with considerable difficulty, and her speech was a bit incoherent. She drank a glass of orange juice, and an hour later seemed as well as ever, though she did not remember having gone to her sister's room. During the following week she felt as well as usual, but on March 9 her husband, when he went to waken her in the morning, found her in coma, and was unable to rouse her. She was seen immediately by Dr. Halsted, who found, as the only abnormal physical sign other than the coma, a palpable tumor in the left upper quadrant of the abdomen. She was taken immediately to the Faulkner Hospital, where I saw her an hour later.

Physical examination showed a well developed and nourished young woman, completely unconscious. Her pulse was not greatly accelerated, temperature normal, blood pressure normal. The pupils reacted to light, the retinæ were normal, there was no choked disc, no stiffness of the neck, no abnormal reflexes. The knee-jerks and plantar reflexes were diminished but present. The heart and lungs were normal. Inspection of the abdomen showed that the left upper quadrant of the abdomen was more prominent than the right, and palpation disclosed a large mass there, extending from beneath the costal margin to about the level of the umbilicus, and from the midline outward into the flank. The mass felt resilient, and smooth. Determination of the blood sugar showed 44 mg per 100 cc of blood. The plasma combining power for carbon dioxide was 51 volumes per cent. The urine showed four plus acetone.

The patient was given one liter of 10 per cent glucose solution. She regained consciousness after receiving about 50 c.c. and was well oriented and replied intelligently to questions before the infusion was completed. She stated that she had been aware for two or three weeks that the left upper quadrant was "fuller" than the right, but had thought, since she felt well, that she was merely growing fat.

The patient was seen in consultation by Dr. E. L. Young, Jr. Because of the hypoglycemia and the size of the tumor, he felt that it was probably a pancreatic cyst, and advised exploratory operation. This was done six hours later. On opening the abdomen a mass the size of a large grapefruit, bluish red in color, and highly vascular, was encountered. It was encapsulated, and across its surface ran a network of large veins. It extended backward to the posterior abdominal wall, to which it seemed fixed. There was no pedicle. A trocar was introduced and intense suction applied, but no fluid obtained. Removal by the anterior approach was obviously impossible, so a small specimen was excised with the electrocautery, and the wound closed. The pathological report on the specimen was as follows: "Carcinoma, growing with moderate speed, originating in an endocrine gland. Whether the tumor is arising from the cells of the islands of Langerhans or from the adrenal cortex cannot be positively determined from present sections. Further studies as to cell origin are being carried out." As a result of those further studies, in which several pathologists collaborated, it was then the consensus that the tumor arose from the adrenal cortex.

The patient made an uneventful though slow recovery from the operation. The fasting blood sugar, determined daily for 18 days, varied between 101 mg. and 41 mg. per 100 c.c. Readings of 60 mg. or less were obtained six times during that period. These low readings were not always accompanied by clinical symptoms of hypoglycemia. The blood counts showed nothing abnormal. Hormone assays March 23 were negative for both prolactin and estrin. The patient continued to menstruate, however, for two months, but since May 27, 1936, has been amenorrheic. Post-operative roentgen-ray treatment was begun March 23, and continued until July 10, utilizing coutard dosage 258 R units. Total R units 3,200. During this treatment, she had no major hypoglycemic attacks, though she occasionally felt dizzy on awakening. Prompt relief was obtained by drinking a large glass of orange juice. Between July 10 and October 13 the attacks of hypoglycemic coma recurred frequently but irregularly, but always responded to intravenous injections of 10 per cent glucose solution. The blood pressure showed a definite upward trend, averaging during October, 150 mm. systolic and 90 mm. diastolic. A mild acne, present at the time of operation, became extremely severe, involving the entire face, the neck, chest and back, and there was marked acanthosis of the axillae. The tongue had become thickened and fissured, and the face, neck and shoulders showed marked thickening of the skin and subcutaneous tissue. Blood non-protein nitrogen and chlorides were normal, and the blood sugar normal when determined. Hormone assays were again negative for both prolactin and estrin. Roentgen-rays of the skull, chest, colon (with barium enema) and kidneys (intravenous pyelogram) showed no evidence of metastases. The mass extended to the top of the fourth lumbar body, and across to the right of the spine. The colon was pushed forward and downward. It was impossible to make out the kidney outlines, but the dye reached the bladder in normal time and in normal concentration.

On October 13, a second attempt was made to remove the tumor, Dr. William E. Ladd operating, by the transabdominal route. Again it was found impossible to remove the growth. The left kidney was identified in close relation to the tumor mass, and the diagnosis of a tumor of the suprarenal cortex seemed confirmed.

Thirty-six hours after operation the patient's temperature rose suddenly and rapidly to 104.4° (rectal), the pulse rate rose from 120 to 180, and the blood pres-

sure fell rapidly to 70 mm systolic and 50 mm diastolic. She became comatose, reviving after intravenous glucose and adrenalin 1-1000 subcutaneously. No evidence of infection could be found. Twelve hours later she was much improved, and on the third day after operation showed a remarkable change for the better. The pulse rate had fallen to 88, temperature 101°, blood pressure normal. During the next two weeks she showed marked general improvement, especially in the skin condition. The subcutaneous thickening almost disappeared, the acne and acanthosis diminished markedly. She left the hospital November 7 in good condition.

During the next two months the patient's condition again grew slowly worse. The acne, acanthosis and subcutaneous thickening increased, though never to their former intensity. The hypertension became more marked, often reaching 190 mm systolic and 120 mm diastolic and occasionally going higher, and the attacks of hypoglycemic coma recurred with increasing frequency. Edema of the lower legs appeared, and shifting dullness in the abdomen could be demonstrated from time to time. During the attacks of coma the patient often became rigid, assuming a posture like that of decerebrate rigidity. At other times the hypoglycemic symptoms consisted merely of perspiration, tingling of the tongue, and moderate analgesia. During one of these mild attacks she was given, instead of glucose solution intravenously, 0.1 cc of adrenalin 1-1000 subcutaneously. The symptoms disappeared with dramatic promptness. Thereafter it was found that a slightly larger dose (0.3 to 0.5 cc) was equally efficacious in the attacks of coma, injection being followed promptly by return to consciousness, so that the patient was able to swallow orange juice within 15 or 20 minutes after the injection.

Despite the general downward progress of the disease, the patient showed surprisingly little loss of strength, and on Christmas day was able to join in practically all the family festivities. Early in January, however, she developed moderate abdominal distention, and rather frequent attacks of headache, and it was decided to use radium treatment. After consultation with Dr. Barringer and Dr. Ewing, of the Memorial Hospital, New York, she was therefore admitted to that institution on January 14, 1937, for treatment. She tolerated radium treatment well, and returned to her father's home to carry on restraint dosage of roentgen-ray. Again irradiation of the tumor was followed by cessation of the hypoglycemic attacks.

On April 9, 1937, the patient complained that during the past week her vision had been failing, especially in the right eye. Ophthalmological examination (Dr. Whitney) showed "Right eye: Disc margins clearly defined, arteries sclerotic, pinching the veins at their crossings, and veins tortuous and distended due to arterial interference. No hemorrhages seen. Left eye: Arteries sclerotic, veins normal size." Dr. Whitney's impression was that the failure of vision was due to obstruction of the venous circulation in the retinae, and also in the central vessels.

The patient's general condition showed little change. The blood pressure varied between 140 and 160 mm systolic, and 90 and 100 mm diastolic. The abdominal distention grew more prominent. There was variable shifting dullness, and intermittent edema of lower legs and ankles. Hypoglycemic attacks of variable intensity, always responding to adrenalin, recurred two or three times weekly. It was, therefore, decided as a last resort to treat her with the extremely powerful roentgen-rays now available at the Huntington Hospital. On admission to the hospital the patient was found to have considerable fever which subsided by lysis in three days. During her stay in the hospital this sudden rise in temperature followed by a lysis recurred twice. Roentgen-ray of the chest gave evidence of metastases in the right lung. The patient had several hypoglycemic episodes while in the hospital but after completion of the treatment they did not recur. Hormone assays of specimens obtained during hospitalization were negative for prolactin and estrin, but positive for the male hormone, quantitation showing between 15 and 20 bird units present.

She grew weaker and more emaciated, developed a harassing cough and marked anorexia, so that it became almost impossible to furnish an adequate amount of carbohydrates. In spite of this deficiency, however, she did not have any more hypoglycemic attacks.

Death came apparently from general exhaustion on July 8. Unfortunately permission for autopsy could not be obtained.

COMMENT

The outstanding symptoms in this patient contrast sharply with those of the first. In one, symptoms were fully established before the tumor could be palpated during laparotomy, while in the other, the growth had reached such size as to cause visible tumor of the abdomen before severe symptoms appeared. This fact alone would suggest that the two tumors were different in nature.

Even more convincing, however, is the hypoglycemia encountered in association with the growth. The patient's blood sugar was normal when it was determined three years previously, and she had had no symptoms suggesting hypoglycemia until 10 days before the tumor was discovered. It is hardly likely, therefore, that the former antedated the latter. The mechanism by which an adrenal cortical tumor produces hypoglycemia is far from clear, and a careful search of the literature discloses no record of a similar association. In fact, hyperglycemia and glycosuria seem to represent the usual disturbance of carbohydrate metabolism in both the adrenocortical syndrome and pituitary basophilism (Cushing,² and Kepler et al.^{1,3,4}) and hypoglycemia has been reported in human adrenal insufficiency by McLean.⁵ Britten and Silvette⁶ found diminution in blood sugar and liver and muscle glycogen in dogs, cats, rabbits, guinea pigs and rats after adrenalectomy, and produced hypoglycemic convulsions and death by removing the adrenals of opossums and marmots. It is not clear, however, whether it is the loss of cortex or medulla which produced these results.

Equally obscure is the mechanism by which small doses of adrenalin relieved the hypoglycemic attacks in this patient. The fact that it did, however, suggests that the low levels of blood sugar were due not to an exhaustion of glycogen reserves, but to an interference with its mobilization.

The further features of special interest are the amenorrhea and atrophy of the breasts, without positive masculinization, the absence of prolan and estrin from the urine, the apparent beneficial effect of irradiation upon the hypoglycemic attacks, and the changes in the skin.

The latter merits, perhaps, special consideration. The skin of the face, which had previously been normal, became thickened, dusky red, and literally covered by small acne papules and pustules. The same process extended downward over the neck, shoulders, chest and back, and in the axillae the hyperplasia of the epidermis was so severe as to produce small lobulated tumors. Following irradiation of the tumor temporary remission of the skin condition occurred.

It is, perhaps, not absolutely certain that the tumor in this case arises from the adrenal cortex. However, the anatomical findings at the second operation and the general agreement of opinion among the pathologists who have examined the sections obtained seem sufficient to eliminate all but the faintest chance that it arises from any other organ. The endocrine character of most of the patient's symptoms suggests a hyperfunctioning gland rather than a non-secreting malignant growth, and the presence of male hormone in the urine is characteristic.

Case 3 A white female of 30 years, single, American, school teacher. She was referred to the Diagnostic Hospital, April 20, 1934, by Dr. Eugene McCarthy of Rumford, Maine, because of blurred vision, of 18 months' duration, polyuria and nocturia for nine months, and amenorrhea for eight months. Dr. McCarthy's history also showed that she had felt unduly fatigued for several years, had "bruised easily, and had noticed an increasing growth of hair on her face for the past year." Polyuria and nocturia, but no polydipsia, had bothered her for about nine months before admission.

Family History One brother died of "sugar diabetes" at the age of fourteen. Two brothers and her father and mother are living. The latter has some kidney trouble.

Past History No operations and no serious illnesses other than diphtheria, mumps and tonsillitis in childhood.

Menstrual History Catamenia began at 11 years of age and was perfectly regular until 1931 when it became irregular for two months and then ceased. At about the same time she noticed that her voice was becoming harsher, that she felt irritable and clumsy and that her hair was growing coarser. She had gained about 25 pounds in weight during the previous two years. She was seen at the Lahey Clinic at that time, and was found to be overweight, nervous and florid. Her heart was moderately enlarged, no murmurs were heard, the aortic second sound was accentuated. The blood pressure was 230 mm systolic, 148 mm diastolic. Abdominal examination was negative. Pelvic examination (Dr. McCarthy) was negative. There was edema of both lower extremities. Eye grounds showed no hemorrhages or exudate, some vascular changes but no arterio-venous nicking. The blood non-protein nitrogen was 32 mg per cent, and the hemoglobin 85 per cent. Blood counts were normal, the coagulation time, 2 minutes 15 seconds. The urine showed a fixed gravity between 1.005 and 1.014. The Wassermann reaction was negative. A diagnosis of primary hypertension was made.

During the next three years the patient became increasingly fatigable, so that latterly it had been necessary for her to stay in bed very often for a day or two. The blurred vision, already mentioned, had been increasing steadily, and for three weeks before entrance had taken the form of a fixed spot before the right eye. The left eye was less affected, but reading, especially of fine print, had become difficult. The eye lids had become slightly puffy and it had become an effort to hold her eyes open. There had been some increase of the hair on the face, and her skin had been constantly discolored with "black and blue" spots. The lower legs, ankles, and feet were constantly swollen.

Physical Examination A red faced, florid, obese young woman with no deformities. The obesity is localized in the abdomen and breasts, and there are fat deposits in the axillary regions. There is pitting edema of the legs and ankles, and a number of discolored areas on the legs. There are several bluish to reddish striae on the medial aspect of each thigh, and in the axillary borders. The cheeks show a fairly rich growth of hair.

The lips are slightly cyanotic, the skin everywhere dry and scaly.

The thyroid is not palpable. The lungs are normal. Heart. The apex impulse is felt 11 cm from the midsternal line in the fifth interspace just to the left of the mid-clavicular line, the right border extends 3 cm from the mid-sternal line, the upper border is at the third rib. There are no murmurs and no arrhythmia. The blood pressure is 220 mm systolic and 160 mm diastolic. The abdomen shows marked *panniculus adiposus*, but is otherwise not remarkable. All normal reflexes are obtained, no abnormal reflexes elicited.

As preliminary diagnoses at this stage of the examination both malignant nephrosclerosis and pituitary basophilism were suggested as possibilities.

A neurological examination by Dr. Golden showed no disturbance of sensation, stereognosis and no incoordination.

Laboratory examinations. Hemoglobin 103 per cent (Sahli), red count 5,500,000, blood clotting time normal. Sedimentation rate 21 mm in one hour. Hinton, Wassermann and Kahn tests negative. Blood calcium 11 mg, cholesterol 375 mg, non-protein nitrogen 52 and 45 mg per 100 cc of blood. Glucose tolerance test. Fasting blood sugar 112 mg, 30 minutes after 100 gm glucose, 246 mg, one hour, 297 mg, three hours, 172 mg per 100 cc blood. Urine tests showed evidence of normal diluting and concentrating function, the phenolsulphonephthalein excretion was 49 per cent in two hours. Albumin varied between 0.1 per cent and 0.15 per cent on numerous examinations, and the sediment showed numerous fine granular and cellular casts, a varying number of white and red cells and on one occasion large numbers of the latter.

Pyelograms were essentially negative. Roentgenograms of the skull showed no evidence of tumor. A tuberculin test was negative. An electrocardiogram was normal except for left axis deviation. The blood pressure remained always above 200 mm systolic and 160 mm diastolic. The basal metabolism was minus 4 per cent on one occasion, and minus 8 per cent on another.

The laboratory findings made the diagnosis of malignant nephrosclerosis a very unlikely one. Pituitary basophilism remained a possibility. The masculinization, however, strongly suggested adrenal cortical tumor. It seemed advisable therefore to explore for adrenal tumor.

On May 11, 1934, Dr. Lahey operated, found and removed a "plum sized tumor" of the left adrenal. Following operation the patient's blood pressure fell to 120 mm systolic and 90 mm diastolic, and continued to fall, despite intravenous injections of saline, glucose and adrenalin. Eschatin was also administered but the patient died apparently from acute adrenal failure.

Autopsy showed removal of the left adrenal gland and extreme atrophy of the right. The latter was found with great difficulty, and weighed less than 0.5 gm. The capsule was thick, the medulla practically absent. Only a few cortical cells were vacuolated. The right ovary measured 3.5 by 1.5 by 1 cm and contained three thin walled cysts, filled with clear fluid. The left ovary was wrinkled and shrunken and measured 2 by 1.5 by 1 cm.

Microscopic examination of the removed tumor showed adenoma. The pituitary body was grossly normal, showing no increase in size. Study of serial sections by Dr. Shields Warren and Dr. Eisenhardt showed no basophilism of the anterior lobe.

Anatomical diagnosis. Marked atherosclerosis, hypertrophy of the heart, dilatation of the stomach and intestines, cholelithiasis, atelectasis of the lower lobe of the right lung, hypertrophy and degeneration of the pineal gland, surgical removal of the left adrenal body.

COMMENT

The clinical picture presented by this patient is very similar to that described by Cushing² as typical of basophilic adenoma of the anterior pitui-

tary body In fact, all the typical symptoms of that condition are present, with the possible exception of osteoporosis and kyphosis, which are not specifically noted in the record In contrast to the other two patients there was even a slight erythremia found, and the history of fatigue and exhaustion is present The one symptom which was not typical was the change in the voice, which, as has been noted, is not described by Cushing as occurring in pituitary basophilism Yet, as in the case described by Walters, Wilder et al⁴ the anterior pituitary body was grossly normal, and serial sections studied by Dr Warren and Dr Eisenhardt revealed no basophilism The discussion of the moot question of the relations between pituitary basophilism and adrenocortical tumor does not lie within the scope of this paper but it seems proper to reemphasize voice change in the female as a possibly important differentiating symptom between the two conditions

Finally, it seems worth while to call attention to the fact that in all three of the female patients reported, menstruation did not appear at the usual age In the first and third, the menarche was unusually early, suggesting prematurity, while in the second patient it was definitely late in appearing This may be pure coincidence in all three cases, but it seems worth noting in a paper which has for its purpose an addition to the records concerning a rare and little understood condition

Case 4 J K, a white 14 year old school boy, admitted to the Diagnostic Hospital, July 21, 1936, because of obesity

Family History Contained no account of obesity in any member of the family There was no family history of malignancy Four siblings are normally developed

Past History The father stated that the boy has never had any illnesses He grew and developed normally until one year before admission

Present Illness During the past year the patient had gained weight very rapidly and his facial appearance had changed markedly due to the obesity and to a dusky reddening of his cheeks On May 18, 1936, he had a sudden convulsive attack lasting from four to six hours accompanied by biting of his tongue and incontinence and followed by vomiting Following the attack he returned to his normal activities and had no more convulsions He complained occasionally of dizzy spells At the time of admission he was attending school, having no scholastic difficulties and playing normally There was no disturbance of vision, no polydipsia, no polyuria, no frequent headaches, no dyspnea nor palpitation, no digestive disturbance and no urinary disturbance The obesity and change in appearance were the factors which led his parents to bring him to the hospital

Physical Examination A 14 year old boy of unusual appearance The face is described as "full moon like" with thick fat folds below the chin and extending upward to merge with the cheeks The latter were dark, cherry red The trunk was markedly obese with prominent deposits of fat on the abdomen and on the back of the neck The arms and legs, however, contrasted sharply in size with the obesity of the trunk, neck and face The skin of the trunk and limbs was dry and slightly thickened and over the inside of the thighs showed marked marbleization Here and there on the legs were a few small bluish spots, typical of subcutaneous hemorrhage The mucous membranes were normal, musculature normal, and there was no evident deformity nor tenderness of bones with the exception of an area over the lower three ribs which was slightly tender to pressure The skull was normal in shape There was no evidence of exophthalmos The pupils were wide, circular and reacted

promptly to light and accommodation. Ocular movements were normal. There was no evidence of disturbance of the third or fifth nerves. The eye grounds, both retinae and the optic discs appeared normal. There were a few hairs on the upper lip. The mouth was normal, teeth normally developed and in good condition. Tongue, pharynx and tonsils not remarkable. Save for the fat deposits previously noted there was no abnormality of the neck. The chest was broad. The lung borders were normal to percussion and there was no abnormal dullness. The breathing was vesicular. Breasts were of feminine configuration due to the fat. The heart was normal in size, sounds not well differentiated, no murmurs. The aortic second sound was moderately accentuated. The pulse was normal in rhythm. It showed increased tension by palpation, the blood pressure was 145 mm of Hg systolic and 90 mm diastolic. The abdomen showed a marked panniculus but was otherwise not remarkable, no masses or organs were palpable. There was marked masculinity of the type of hair growth and several dark red striae were noted on both sides of the abdomen. There was considerable hair growth in the lumbar region of the back. The genitalia were markedly hypoplastic. The extremities were freely movable and showed no deformities. Reflexes were all normal with the exception of the cremasterics which were exaggerated equally on the two sides. There was no disturbance of sensation.

Laboratory Examinations The urine was normal and a test for prolan in the urine was negative. The blood showed a hemoglobin of 89 per cent, red blood cell count 5,430,000, Wassermann and Hinton tests negative. The basal metabolic rate varied in a number of observations between minus 20 per cent and minus 40 per cent. A blood sugar tolerance was performed with difficulty, the fasting blood was not obtained, but the values for one, two and three hour specimens after ingestion of 100 gm of glucose were 240 mg, 299 mg and 230 mg respectively. The corresponding specimens of urine showed glycosuria in every specimen. Roentgen-ray plates of the pelvis and skull showed no pathologic changes.

A diagnosis of pituitary basophilism was made and he was given four treatments with roentgen-ray to the pituitary region, with complete relief of the headaches and slight loss of weight. There was little other change in his condition for the next four months. He then developed a small but deep ulceration of the anterior surface of the left lower leg which healed very slowly. His blood pressures during the four months had varied between 120 and 140. The boy seemed cheerful and had no complaints. Intravenous pyelograms gave normal findings. On April 10, 1937, it was noted that his condition was unchanged, but a few days later he developed a second ulcer just below the first. This increased rapidly in size and became as large as the palm of one's hand and discharged purulent material. The boy was, therefore, readmitted to the hospital where it was noted that the red color of the face was even more dusky. The abdominal striae were more pronounced and striae had appeared in both axillae and on the left upper arm. He had regained the weight lost after the first roentgen-ray treatments. The skin of the arms and legs had become very dry and thick and varied from bright red to bluish red in color. The left ankle was edematous and motions of the foot were painful. The fat deposits previously described had definitely increased.

The fasting blood sugar on two different days was 282 mg and 245 mg per 100 c c. There was slight glycosuria. He was given insulin 25, 15 and 20 units with a reduction of sugar to normal. The omission of the insulin was not followed by an increase in the blood sugar and the boy seemed more alert. There was, however, considerable general weakness. Roentgen-rays, May 22, showed definite osteoporosis. The basal metabolism was minus 27 per cent. The glucose tolerance showed: Fasting 124 mg, thirty minutes after 100 grams of glucose, 185 mg, one hour, 249 mg, two hours, 299 mg, and three hours 230 mg. The fasting and 30 minute specimens

of urine were sugar free. The one hour specimen showed a trace of sugar, the two hour 3 per cent and the three hour specimen 32 per cent. The sedimentation of the blood was 15 mm in one hour (Westergren).

Roentgen-ray of the skull showed no evidence of tumor. The basal metabolic rate was always subnormal. Temperature, pulse and respiration were normal. Blood platelets 409,000, phosphatase 438 units.

The patient was transferred to the Massachusetts Memorial Hospital for exploration of the adrenal gland. His condition at the time was extremely poor and he failed to rally postoperatively, death occurring without further significant developments.

The chief findings at autopsy were as follows. There was a large symbiotic ulcer on the lateral aspect of the left leg. The right lung was partially collapsed and the right lower lobe contained a multilocular abscess approximately 4 cm in diameter. It contained about 5 cc of thin, granular, purulent material. The liver was pale yellowish brown, lobulations poorly defined, distinctly greasy and somewhat friable. The pancreas weighed 100 gm and showed many scattered subcapsular foci of fat necrosis varying from 3 to 10 mm in diameter. The pancreatic duct showed no evidence of obstructive inflammation or other pathologic lesion. The adrenals together weighed 15 gm and were distinctly enlarged although they showed no specific adenoma nodules. The right adrenal measured approximately 6 cm by 3 cm by 6 mm. The left adrenal was distinctly mal-formed and larger than the right. The upper portion seemed normal while the lower portion formed a well defined beaver-tail-like accessory lobe. It measured 7 cm in length, 3 cm in diameter and had an average depth of 6 mm. Serial sections showed a normal gross relationship between the medulla and cortex. No adenomatous or other tumor nodules could be seen. The cortical tissue was pale yellowish brown and showed less lipid storage than is normally observed. The genitalia were infantile. The thymus was so extremely small and atrophic that it was found with great difficulty. Only the slightest remnants suggesting thymic tissue were discovered. The thyroid was normal in size, shape and position and appeared normal on section. The pituitary was distinctly shrunken, measured approximately 1 cm in its long axis and 4 mm in its diameter. It was distinctly more dense and fibrous than normal. At its left lateral pole the cut surface presented a distinct nodule approximately 3 mm in diameter of a brighter yellow than the surrounding tissue and having no other specific characteristic. The vertebrae showed a marked osteoporosis so that in many places the dark reddish brown marrow could be seen through the outer cortical bone which could be easily incised with a scalpel.

Pathological Diagnosis Adrenal hypertrophy, adenoma of the anterior pituitary lobe, chemical pancreatitis with extensive fat necrosis, thymic atrophy, testicular atrophy, fatty degeneration of the liver, cellulitis of the neck, symbiotic ulcer of left leg, toxic lymphadenitis. The histological findings are not yet available. Assay of the liver, adrenals and testicles for estrin showed more than 500 m u in the liver extract, but was negative in the other two tissues. No follicle stimulating or luteinizing hormone could be demonstrated.

COMMENT

Clinically, this patient presented the typical picture of pituitary basophilism described by Cushing,² and the pathological findings, though not complete, furnish confirmatory evidence. Postulating a primary basophilic adenoma, the other endocrinopathies can be explained as secondary manifestations of disturbed pituitary function, while no such logical sequence can be constructed if the adrenal hypertrophy be regarded as the primary

disturbance In adrenal hypertrophy virilism, not infantilism, would be expected No significance is attached to the hormone assays they are reported as a matter of record

SUMMARY

Four cases, all presenting certain similar features suggesting the adrenal cortical syndrome, are presented In two, the diagnosis was confirmed by operation or autopsy In a third, the diagnosis seems reasonably established by operation, and in the fourth, an adenoma of the anterior pituitary lobe was found at autopsy The histories, physical and laboratory findings together with the findings at operation or autopsy are reported

My thanks are due to Drs Prather, Hazard, Lahey, Warren, Eisenhardt and Branch for their generous cooperation in furnishing surgical and pathological reports I also wish to thank all the staff members of the New England Medical Center who contributed to the diagnostic studies herein reported

AUTO PASSIVE TRANSFER IN ALLERGY *

By D MURRAY COWIE, M D , F A C P , *Ann Arbor, Michigan*

ON May 18, 1936 Samuel W , 52 years of age, presented himself for allergic studies because of an uncontrollable asthma that had been going on for five years. He had been examined elsewhere by the scratch method. The reactions secured by this method had not been satisfactory, in that after carrying out the eliminations suggested by these tests no relief was experienced.

On intradermal examination with standardized allergens² the patient reacted negatively to 80 out of 96. Of the 16 positive reactions only five could be considered unquestionably positive: feathers, black pepper, sheep wool, mushroom and corn.

There was no question concerning the allergic nature of this patient's asthma. That being the case there was every reason to believe that his circulating blood was laden with allergic antibody.

In the prosecution of scientific observations on clinical allergy, three prime factors must at all times be considered: antigen, antibody, tissue cell. The nearer we come to being able to control these factors the more trustworthy will be the interpretation of the results of experimentation. At least two of these factors may be satisfactorily controlled, antigen and antibody. The tissue cell is, and probably always will be, a variable and possibly an indeterminable factor.

The patient Samuel W was endowed with the two essential somatic factors: antibody, tissue cell. Why, then, did his skin not react to specific antigen? Such instances are not uncommon. Specific sensitivity in such individuals is proved by the well known Prausnitz-Kustner phenomenon, brought about by the passive transfer of the allergic person's serum into the skin of a non-specifically allergic person, where, after a certain latent period, it locally passively sensitizes the skin, and when the third factor, specific antigen (allergen) is injected into it a characteristic intradermal allergic reaction develops. The Prausnitz-Kustner phenomenon was demonstrated by use of the patient's (Samuel W) serum.

To return to the question, why did the patient's skin not react to the injection of the specific antigen, to which we had now proved he was sensitive? What difference could there be in his skin to that of a recipient's which had been proved to be non-specifically allergic but could be made passively so by the introduction of allergic serum from another person? May there be, in such instances, some unusual variation in the quantitative rela-

* Received for publication August 12, 1937

tions of the circulating antibody? May there be something defective in the skin mechanism? Had something occurred to make the patient's skin less sensitive than it may have been at some other time?

I *To test the first hypothesis* it was a simple matter to inject the patient's skin with his own antibody laden blood serum. If his skin cells were capable of being passively sensitized a reaction should occur when specific antigen is injected into the treated area because, to any antibody already circulating through the skin, there would be added concentrated antibody. When this experiment was carried out a typical intradermal allergic reaction occurred. I have designated this phenomenon as *auto passive transfer*¹ because the patient's own passively sensitizing blood serum is transferred into his own skin, where it sojourns for a certain time, then disappears. This is suggestive, but not positive, evidence that the failure of the skin to react, in the untreated areas, is due to insufficient antibody coming to it.

METHOD

The allergens (antigens) used were standardized² in my laboratory by Dr. John J. Engelfried to an exact nitrogen content of 5 mg. per cent, the same batch of allergen being used for comparative observations. Exactly 0.03 c.c. is injected intradermally as the test dose. This is done very carefully, infiltrating the skin slowly so as not to induce a traumatic reaction.

The Syringe and Needle. New B. D. Tuberculin Syringes and No. 26 (27 better) gauge rustless needles are used. After use they are carefully rinsed in warm distilled water. The needle is removed and the collar carefully cleaned with a cotton applicator and the syringe again thoroughly rinsed in distilled water. After this suction is applied by a Chapman pump which aspirates distilled water through the barrel. Alcohol (96 per cent) is then rinsed through syringe and needle to remove all traces of water. The plunger and barrel are separated and allowed to dry in the air. The needles are blown out with dry air and after checking the points, are put singly into small glass tubes between plugs of cotton to be sterilized. The syringe plunger and barrel (apart) are wrapped in heavy wrapping paper. The needles and the syringes are sterilized by placing them in an oven at room temperature, raising the temperature to 220° C., cooling to 100° C., again raising to 220° C. and allowing to cool. The needles are checked with a magnifying glass and specially sharpened, by the Department of Engineering, after they have been used approximately 10 times.

All this is done to destroy traces of allergen left in the syringe and needle, and to avoid the presence of moisture that would dilute the allergen. In other words the glassware and needles used in this investigation were chemically as well as bacteriologically sterile. Formerly our syringes and needles were rinsed in dichromate cleaning solution. This was hard on the needles. We have returned to this practice, plus the above details, as the rustless needles now used withstand this action fairly well.

Serum Transfer. A precise amount, 0.05 c.c., of the patient's serum is injected intradermally into as many skin sites as are desired. In our present routine of *auto passive transfer examination*, 32 transfers are made on alternating days. The sites or areas of transfer are tested for specific sensitivity, after 24 hours, by the intradermal injection of the standard amount of allergens (0.03 c.c.). In quite a percentage of passive transfers there is an immediate reaction following the injection of serum that cannot be differentiated from a positive allergen intradermal reaction. It disappears in the ordinary time. Its nature is considered in another paper.

Recording the Reactions The reactions are measured in millimeters, with fine pointed dividers, in two opposite or perpendicular diameters. The average of the two readings is charted. The wheal and the area are both recorded on the working sheet. The area measurement of course includes the diameter of the wheal. The character of the wheal with regard to the number of pseudopods and the degree of edema is also recorded as well as the color of the area and its degree.

W = Wheal E + and E = marked or slight edema

P 1, 2, 3, or 4 = the number of pseudopods

A = Area The number gives the average diameter from which the area surface may be computed ($a = \pi r^2$)

R = red, R + very red, R — less red

F = faint, F = very faint, F = very very faint

M = Mottled

Thus the following record, Ragweed $W 12 P_2$ means a wheal of 12 millimeters average diameter with two pseudopods and a red area 31 millimeters average diameter or, as in the following tables only the average diameters of the entire reaction at the time specified are recorded as 35 R +, 36 R —, 30 F. These are the 15 minutes, 30 minutes and one hour readings. Some reactions are, for the greater part, mottled, (M), particularly about the periphery. Measurements of these are made with the dividers to the edge of unquestioned color. Observations are all made at exact time intervals announced by a mechanical timer. Seldom were measurements made excepting by myself, to assure no interference by the personal equation.

OBSERVATIONS

A few illustrative observations on *auto passive transfer* are recorded in the accompanying tables which are self explanatory.

Case 1 The first case is that of Samuel W, 52 years old, referred to in the opening paragraph. I made 17 transfers of the patient's serum into the skin of his back on June 24, 1936, 8 on July 3, and 16 on July 13, a total of forty-one. The following days the same number of standard food allergens² was injected intradermally into these transfer sites. These allergens were selected from a list of those to which the patient had failed to react on the regular intradermal examination. There resulted eight unquestioned positive reactions. These are arranged in table 1 in the order of the degree of reaction together with 14 of the negative reactions. Accordingly eight additional offenders were found by this method of examination, one of which, cucumber, was of undoubted clinical significance. The negatively reacting allergens serve as a good control.

Case 2 Mrs Dora R, 38 years old, suffering with severe asthma, was given 96 intradermal tests in our Sensitization Clinic. No relief was secured from putting into effect the eliminations indicated by this examination. I had her sent to my laboratory where I made 11 auto passive transfers into the skin of her back (November 17, 1936). The following day these sites were tested by the intradermal injection of 11 allergens she had failed to react to. Eight of these were found to be positive (table 2).

| Wheat Proteose | 0 | 17 R | | | |

Case 3 Mr G V, 65 years old, who showed multiple sensitization in 1934, returned for reexamination in February 1937. The putting into effect of eliminations suggested by his first examination had brought relief from his cutaneous symptoms. I made 96 intradermal tests and found him sensitive to nine. To test the effect of auto passive transfer I made nine transfers of his serum into the skin of his arms (February 22, 1937) and tested these sites the following day to nine food allergens, to eight of which he had given negative reactions on my last intradermal examination but to which he had given positive reactions in 1934. He gave definitely positive reactions to three of these (table 3).

Case 4 Willard O, 12 years old, was referred from the Otolaryngology Clinic for allergic studies because of allergic rhinitis. In 1936 he was given 32 intradermal tests and reacted to two allergens, wheat leucosin and pineapple. In February 1937 he reacted to the same two plus feathers. On March 1 we made 40 auto passive transfers into the skin of his back and tested these sites the following day by the intradermal injection of allergens he had failed to react to. He reacted to 12 of these as shown in table 4.

Case 5 Mrs Cassie M, 51 years old, a case of asthma, was referred from Dr Sheldon's Allergy Clinic for auto passive transfer studies, May 21, 1937 This patient had been given 172 intradermal tests in August 1936 and had reacted positively to 85 She returned for reexamination in May 1937 because of a continuance of her asthma Tests for the pollens and some molds were given Only slightly positive reactions to four were obtained Oat grass +, rye grass +, poplar ± and June grass ± Because of the faint reactions these tests were repeated with the same result Table 5 records the comparative intradermal and ophthalmic tests and those of the auto passive transfer areas Unfortunately rye grass and poplar allergens were not included By reference to table 5 it will be seen that she gave definite reactions to nine allergens, including two she had reacted to, slightly, before

TABLE V

Mrs Cassie M , Age 51, Asthma

May 21, 1937

| Allergen | Test 5-18-37 mm | Auto Passive Transfer Exam 5-21-37 mm | Allergen | Intradermal Test 5-18-37 | Auto Passive Transfer 5-21-37 |
|------------|-----------------------|--|---------------------------------------|--------------------------------|-------------------------------------|

It was our understanding when this patient was sent to us that she had failed to react to the entire list of 172 allergens with the exception of those mentioned above, accordingly we had prepared her skin the day previous for 47 auto passive transfer tests. There were therefore 35 sites left, these we tested with food allergens. It is of interest to record the results (table 6), even though we do not have an intradermal control, because of the many unusually marked reactions obtained, and to illustrate for comparison how the skin may react under these conditions. I am also recording in this table the results of tests done ten months previously with the same allergens. The notation, however, is different. It is based on the appearance of the wheal without reference to the area. A wheal of about 5 mm in diameter is recorded ±, 8 mm +, 10 mm ++, 13 mm +++, 13 mm or larger with pseudopods ++++. It is our custom to measure both wheal and area and to record a wheal of 8 mm without appreciable area as negative. A wheal of 10 mm as ±.

Case 6 Mrs Irene R, aged 36, a case of asthma, was referred to me from the Clinic of Internal Medicine for auto passive transfer examination because she failed to react to any of the pollens. We made 39 auto passive transfers to the skin of her back and the following day injected seven pollen allergens and 32 food allergens. All the tests were negative.

Case 7 Robert S, 4 years old, a case of asthma, was tested with 96 antigens intradermally on March 1, 1937. He reacted to feathers only (19 mm). On March 18, I made 16 auto passive transfers and tested the areas the following day with 16 food allergens. He reacted positively to two of these, orange, 15 mm, and potato 17 mm. The entire examination had been quite a trial to this rather nervous little chap and tears constrained me to proceed no further.

Comment These observations, I believe, prove beyond question that an allergic person's skin which fails to react to specific allergen can be passively sensitized with his own serum, and they suggest that the inactive skin is made to react by bringing more specific antibody to it. This demonstration that an allergic person's inactive, or refractory, skin can be passively sensitized with his own serum and made to react to specific allergen, suggests that the skin inactivity may be due to a quantitative defect of circulating antibody, or to some inability of the skin cells to take up antibody as it circulates through it. However, it is of further interest to know whether an allergic person's skin that *does react* to the injection of specific allergen may be made to react more vigorously by this mechanical introduction of

more and concentrated specific antibody into it The reactions assembled in table 7 seem to show that such more vigorous reactions may be thus induced, and add evidence that quantitative antibody influences may be responsible for failure of an allergic person's skin to react There is, however, an instance where just the opposite result occurs, No 8 More observations are necessary before this point can be considered definitely settled

This same phenomenon, described in connection with auto passive transfer, may also be induced through passive transfer That is a positive intradermal reaction may be enhanced by the introduction of more specific antibody from another person into the skin This is shown in table 8

May there be something defective in the skin mechanism? My observations on the Prausnitz-Kustner phenomenon seem to demonstrate clearly that there is something in the skin mechanism itself that may be responsible for the degree of the skin reaction It is easy to demonstrate that the skin

of different skin donors, or recipients, for passive transfer may vary greatly in its ability to react to allergen^{3 4} For example, I record in table 9 two instances where the skin was negative to the intradermal test before passive transfer was done After passive transfer, one reacts more vigorously than the other or does not react at all, yet exactly the same amount of antibody and the same latent period elapsed in each case before the testing was done It is also shown in table 9 that reactions in auto passive transfer areas are as likely to occur as they are in passive transfer areas Donor H's skin reacted oftener and more vigorously than did donor E's, and auto passive transfer areas reacted as frequently and as vigorously as the passive transfer areas of donor E

Had something occurred to make the patient's skin less sensitive than it may have been at some other time? Reference to tables 3 and 4 furnishes illustrations of a skin, which was active a year or several months before, losing its ability to react and being made to react by means of auto passive transfer

TABLE IX

Different Reaction Ability of Different Skin Donors to Allergen on Passive Transfer

| Allergen | Intradermal Test on Skin Donor H | Intradermal Test on Skin Donor E mm | Passive Transfer Test on Skin Donor H mm | Passive Transfer Test on Skin Donor E | Auto Passive Transfer |
|-------------|---|--|--|---|-----------------------------|
| Silk | 0 | 0 | 51 | 0 | 0 |
| Cotton Seed | 0 | 0 | 31 | 19 | 27 |
| Date | 0 | 0 | 31 | 20 | 13 |
| Salmon | 0 | 0 | 38 | 0 | 28 |
| Vanilla | 0 | 0 | 25 | 0 | 0 |
| Cherry | 0 | 0 | 19 | 0 | 0 |

These observations seem to indicate that failure of an allergic person's skin to react may be due to one or a combination of two things—quantitative antibody influences, some change in the skin mechanism whereby specific antibody is not properly brought to it or is kept away from it

Determination of the quantity of circulating passively sensitizing antibody To carry this work further some method for quantitating or titrating circulating sensitizing antibody must be worked out, investigated and found to be satisfactory

By using known amounts of specific antigen (allergen) the amount of antibody in a given serum may be determined by an absorption experiment It has been shown in this laboratory and elsewhere ^{3, 4, 5, 6} that specific antigen

TABLE X

Sensitizing Antibody Titer

Robert M, 11 years Short Ragweed

| No | Antibody + Antigen | | | Reaction in Passive Transfer Area mm |
|----|--------------------|------------|----------------------|--|
| | Serum cc | NaCl cc | Antigen mg % prot | |
| 1 | 0 35 | 0 15 | 20 | 0 |
| 2 | 0 35 | 0 15 | 10 | 0 |
| 3 | 0 35 | 0 15 | 5 | 0 |
| 4 | 0 35 | 0 15 | 2 5 | 26 R |
| 5 | 0 35 | 0 15 | 1 | 43 R |
| 6 | 0 35 | 0 15 | 0 | 43 R+ |

- 1 Original antigen extract 0 666 mg per cc in sterile 0 85% NaCl solution 0 15 cc of this solution + 0 35 cc of serum = 20 mg % of antigen
- 2 1 cc No 1 + 1 cc of sterile 0 85% NaCl solution 0 15 cc of this solution + 0 35 cc serum = 10 mg % of antigen
- 3 1 cc of No 2 + 1 cc sterile 0 85% NaCl solution 0 15 cc of this solution + 0 35 cc serum = 5 mg %
- 4 1 cc of No 3 + 1 cc sterile 0 85% NaCl solution 0 15 cc of this solution + 0 35 cc serum = 2 5 mg %
- 5 0 8 cc of No 4 + 1 2 cc sterile 0 85% NaCl solution 0 15 cc of this solution + 0 35 cc serum = 1 mg %

destroys or renders inactive sensitizing antibody Varying amounts of specific allergen (antigen), short ragweed for example, are mixed with a given amount of the serum to be tested The mixtures are made isotonic with 0.85 per cent sodium chloride, incubated at 37.5° C for one hour without preservative, and 0.05 c c of each dilution is transferred to a recipient's skin as previously described In table 10 the strengths of the ragweed antigen added to the 0.35 c c of serum are indicated by their content respectively of 20, 10, 5, 2.5, and 1 milligram per cent protein In this instance 5 mg per cent (0.025 mg) of short ragweed protein completely neutralizes all the antibody contained in 0.35 c c of the patient's serum Antigen of the strength 2.5 mg per cent does not The actual amount necessary is therefore somewhere between these figures Table 11 shows the same thing

TABLE XI
Sensitizing Antibody Titer

M. M., 32 years Short Ragweed

| No | Antibody + Antigen | | | Reaction in Passive Transfer Area mm |
|----|--------------------|----------|-------------------|--------------------------------------|
| | Serum c c | NaCl c c | Antigen mg % prot | |
| 1 | 0.7 | 0.3 | 10 | 0 |
| 2 | 0.7 | 0.3 | 5 | 0 |
| 3 | 0.7 | 0.3 | 2.5 | 42 F |
| 4 | 0.7 | 0.3 | 1 | 37 R |
| 5 | 0.7 | 0.3 | 0 | 42 R |

Walzer and Bowman⁶ found that the admixture of equal parts of "the strongest pollen solution available (0.4 mg N per c c)" with a hay fever patient's serum, completely neutralized the antibody only after several hours incubation Coca and Grove⁵ were unable to quantitate the reagin present in a given serum by the serum dilution passive transfer method If in carrying out a comparative observation the same donor's skin can be used, and too much time has not elapsed between determinations, an idea of any change in the quantity of circulating antibody that has occurred during that time may be obtained Change to another skin donor is not permissible because of the variability in the reactivity of different skins Table 12 illustrates this point Ten milligrams did not neutralize all the antibody according to J. D.'s skin, but between 3 and 5 mg neutralized it according to D.'s skin and somewhere between 5 and 10 mg according to B.'s skin This again illustrates that the human tissue cell is a variable factor

The sensitivity of the skin of an allergic person varies from time to time Especially is this true of food allergy, depending as it does on the inclusion or omission of the specific food from the diet Accordingly in carrying out quantitative observations by means of the Prausnitz-Kustner

TABLE XII

Sensitizing Antibody Titer

Showing that the human tissue cell is a variable factor

passive transfer or the *auto passive transfer* method, there are many things that must be carefully taken into consideration, otherwise information based on the results may be fallacious

SUMMARY AND CONCLUSIONS

1 Evidence is produced to show that the skin of an allergic child or adult which fails to react to the intradermal injection of allergens to which he is sensitive may be made to react by the passive transfer of his own blood serum into his own skin

2 I have designated this phenomenon as auto passive transfer because the patient's own passively sensitizing serum is transferred into his own skin where it sojourns for a certain length of time, then disappears

3 The method of procedure is described and a few illustrative cases presented

4 These observations seem to show that the failure of an allergic person's skin to react to specific allergen is dependent upon one, or the combination of two factors, something at variance with the quantitative nature of the circulating antibody, something at variance with the skin mechanism whereby specific sensitizing antibody is not properly brought to it or is kept away from it

5 In some instances, at least, reactions to specific allergen occur as frequently and as vigorously in auto passive transfer areas as in passive transfer areas Usually, however, passive transfer areas give the larger reactions It seems that reactions are as likely to occur in auto passive transfer as in passive transfer areas

6 Positive intradermal reactions are very often enhanced by auto passive transfer

7 Auto passive transfer may be used as a practical method of examination when passive transfer is indicated It overcomes the necessity for a

control intradermal examination of the skin donor, or recipient. This shortens the examination period 50 per cent, on the other hand it inflicts more tests on the patient.

8 The *auto passive transfer* method cannot, and is not intended to, replace the Prausnitz-Kustner method. It is an interesting phenomenon and I believe it opens up a new approach to the study of the fundamental principles of skin allergy. If future observations confirm those here recorded, difficulty in securing a satisfactory skin donor for passive transfer will be avoided.

9 The difficulties of quantitative estimation of allergic antibody are considered, and a method presented.

SOME PHYSICAL PHENOMENA ASSOCIATED WITH THE ANXIETY STATES AND THEIR RELATION TO HYPER- VENTILATION *

By WM J KERR, M D , F A C P , JAMES W DALTON, M D , and PAUL A
GLIEBE, M D , *San Francisco, California*

DURING the past several years the world, in general, has been undergoing critical social, moral, and economic changes, and, in the present state of upheaval, an ever-increasing number of patients are observed who present a symptom-complex which is intimately associated with the individual's struggle for security, for independence, or for whatever state is presumed to assure the spiritual and material happiness of the individual. This symptom-complex is essentially a representation of the interaction between emotional and physiological factors. While not seen exclusively among persons suffering from psychoneuroses, this symptom-complex is frequently found in such persons, and its manifestations are designated as anxiety states. Patients presenting the well-known pattern of symptoms haunt the offices of physicians and specialists in every field of medical practice. They are often shunted from one physician to another, and the sins of commission inflicted upon them fill many black pages in our book of achievement.

Our present interest in this problem arose from the study of a group of patients who in addition to their anxious tensional states were suffering from so-called "convulsive seizures." We observed that they presented symptoms and signs of tetany associated with hyperventilation. During this investigation it became apparent that there are also a large number of patients (variously estimated as one-fourth to one-third of the patients seen in general practice) who have, as localized manifestations of the same mechanism, a variety of symptoms referable to many structures in the body, and in whom hyperventilation precipitates and maintains a state of hyperirritability approaching clinical tetany. The symptoms may be so well localized in some cases that local disease is suspected without discovery of universal functional disturbance.

In order to make clear the manner in which psychological disturbance alone can produce symptoms of tetany, the well known causes of tetany will first be reviewed briefly.

The symptom known as tetany is usually defined as a painful, tonic

* Presented in brief at a clinic on the same subject, given at the Philadelphia meeting of the American College of Physicians on May 1, 1935.

From the Divisions of Medicine and Psychiatry, University of California Medical School, San Francisco

spasm of the muscles of the extremities. Many studies have been made in an effort to explain the manifestations which occur in the better known types of tetany. In general, tetany is thought to depend (1) on the degree of mobilization of the calcium ion, probably the diffusible fraction, (2) on the presence of alkalosis, or (3) on the existence of tissue anoxemia.

In hypoparathyroidism, there is a reduction of the serum calcium, an increase in the carbon dioxide combining-power, and an increase in the serum phosphorus. When a state of hypocalcemia and alkalosis is present, the degree of tetany depends upon the threshold of the particular patient to the stimulus he receives.^{1 to 4}

In gastric tetany, alkalosis results from loss of hydrochloric acid from the stomach,^{5, 6} and increase in the carbon dioxide combining-power of the blood⁷ because the following reaction takes place

It is suggested that in this disturbance in the chemical state of the blood, the diffusible calcium becomes fixed, and that the spasms which occur are really the result of alkalosis and hypocalcemia.^{3, 5} Definite proof of this statement is lacking, however, and alkalosis alone may be the cause of the symptom.

In infants suffering from tetany, reduction of the serum calcium follows an increase in carbon dioxide combining-power. There is one major difference, however, i.e. that the serum phosphorus rarely deviates from the normal.^{1, 8}

The so-called "bicarbonate tetany" can be induced in adults without the reduction of the calcium ion if a large enough quantity of sodium bicarbonate is ingested. If the H-ion concentration is reduced to 10^{-6} or less, tetany will occur. Although there is some disagreement,⁹ it is stated¹ that the ingestion of any anion which will combine with calcium to produce an insoluble salt, will cause tetany. Included among these anions are carbonate, phosphate, citrate, oxalate, and fluoride. It is known that in normal individuals the production of tetany by the ingestion of phosphates can be accomplished only by the use of large amounts of the salt, whether it be acid, alkali, or neutral salt. In such circumstances,¹⁰ the phosphates and the sodium ion concentration are increased, and the calcium and magnesium ions are decreased.

In rickets, during the healing stage, a form of phosphate-tetany occurs. In this state the interrelation of the calcium and phosphates is more labile, and the ingestion of normal amounts of phosphates is enough to depress the serum calcium and cause the spasm to take place.¹

In discussing hyperventilation tetany, it is important to understand the physiological background which makes this symptom-complex more evident in anxious individuals than in others with more stable emotional control.

That the state of hyperventilation and its subsequent effects are not a

discovery of the present century, is well illustrated by the passage quoted below which was suggested to us by Dr Sanford Larkey

Melancholoke folke are commonly giuen to sigh, because the minde being possessed with great varietie and store of foolish apparitions, doth not remember or suffer the partie to be at leisure to breathe according to the necessitie of nature, whereupon she is constrained at once to sup vp as much ayre, as otherwise would srue for two or three time, and this great draught of breath is called by name sighing, which as it were a reduplicating of the ordinary manner of breathing In this order it falleth out with louers, and all those which are very busily occupied in some deep contemplation Sillie fooles likewise which fall into wonder at the sight of any beautifull and goodly picture, are constrained to giue a great sigh, their will (which is the efficient cause of breathing) being altogether distracted, and wholly possessed with the sight of the image

—DuLaurens, Andre

A Discovrse of the Preservation of the Sight, of
Melancholoke diseases, of Rheumes, and of old
age London 1559 Verso, o3s

It will also be remembered that Shakespeare, in his *Seven Ages of Man*, in "As You Like It," refers to "lovers sighing like a furnace"

With these reminders that much of that which is to be discussed was described long ago, it is our purpose to re-word these phrases and apply new interpretations which will clarify the understanding of a problem that has been heretofore avoided or regarded superficially Likewise, it is hoped that the plan of study and of treatment which is to be described will be used as an aid to the solution of such problems in the future

A radical departure is made by those who believe that a physical syndrome can be provoked by an emotional state such as anxiety In the past, most physicians have consciously or unconsciously, felt that such symptoms were manifestations of an overactive imagination, or, more likely, that they represented an attempt on the part of the patient to gain the center of attention of his family, friends or physician However, there is no doubt that these patients with anxiety do suffer actual symptoms such as pain, as the result of changes in function or even in structure which have taken place because, and only because, of the preexisting anxiety This latter thesis will doubtless be met with considerable opposition from many internists and psychiatrists It is our opinion that emotional conflicts which are permitted to continue for a considerable length of time predispose the individual to structural disease It is presumed, therefore, that a chronic state of anxiety induced by such a conflict is of greater importance than is generally believed, and that its eradication, or more properly its resolution, is of utmost importance in preventing future structural, or so-called "organic," disturbances The philosophical implications of this concept are consistent with modern knowledge of many symptom-complexes in medicine

In offering an explanation of the interaction of anxiety states and the physical syndrome, we shall present the histories of a series of patients to

illustrate various combinations of the phenomena which have been erroneously interpreted as syndromes of organic disease that they resemble

Symptoms, regardless of whether they are of somatic or psychic origin, are manifestations of disturbance of function. Although disorders of the psyche are known to occur without any recognizable effects on the soma, it should be made clear that no attempt will be made to divorce them. Disorders of the psyche represent disturbed functions of the total personality. Further, prolonged influence of disturbances in function in certain parts of the brain, notably the hypothalamus and basal nuclei, induces functional changes throughout the body which, if continued, may lead to local peripheral structural changes. In turn, these peripheral alterations in function and structure promote further psychical reactions which tend to aggravate the total process. Thus syndromes now well recognized are established, and the true basic nature of the malady as a primary disturbance in function is erroneously classified as being of organic or structural origin.

The concept which has been described is the outgrowth of the study of patients in whom the symptoms of grand mal, of angina pectoris, of peptic ulcer, of constriction of the sphincters of the esophagus, bladder and other hollow organs, and of Menière's syndrome, were found to be psychogenic and not primarily on local or structural bases. These patients were observed to respond to therapy directed toward decreasing nervous irritability by the use of medicaments and diet intended to diminish tissue alkalosis and tissue anoxemia. Later their symptoms were further alleviated by more prolonged methods of psychotherapy.

In the group of patients reported, the organic diseases suggested by their symptoms were ruled out by the usual diagnostic procedures, so that each was known to suffer from a "pseudo-disease" the symptoms of which, in all cases, were the result of the same cause—*anxiety*. It is believed that in the convulsive state there exists a generalized nervous phenomenon, of nervous origin, with explosive stimulation of the patient's muscular system. In the other disturbances a similar but more localized reaction occurs. It is an hypothesis that these various syndromes are the result of an increase of central (nervous) and general (humeral) irritability which, in some instances, leads to tetanoid contractions or to spasms in a specific locality that, in all probability, are initiated by tension and nervous strain subsequent to *anxiety*. It is really made possible by a physical and a chemical disturbance resulting in a localized tissue alkalosis, a tissue anoxemia, or a tissue hydremia.

Viewing these symptoms as manifestations of tetanoid contractions, or of peripheral nerve stimulation, or of both, diagnostic studies were undertaken which showed that this type of tetany differs from the recognized types of tetany, and is not associated with disturbances in calcium metabolism. Rather, it depends upon the other electrolytes and their relation to the acid-base balance ^{2, 5, 11, 12, 13}

THE EXAMINATION OF THE PATIENT

Among the tests performed, an exercise in hyperventilation¹² is included for several reasons. It is well to establish the diagnosis in this manner because repetition of the symptoms emphasizes to the patient the value of control of respiration. Likewise, he is relieved to discover that his symptoms are not those of organic disease, for it is demonstrated that he can produce them at will. Often the patient is so impressed and comes to have such faith in the physician's ability that contact or "rapport" is easily established, making psychotherapy more effective. The method is of value because studies of the alkaline shift in these patients can be made, and the efficacy of the various forms of treatment can be compared from time to time. In some instances, when the exercise is again given at a later date, it is observed that the induction-time, or period from beginning of the exercise to the appearance of the first symptoms, has increased, and that the intensity of the reaction has diminished. It is understood that normal persons will show the same symptoms if hyperventilation is continued long enough. The point of importance is the ease with which these patients are thrown into a state of tetany because they are on the threshold of attacks periodically or constantly.

The procedure is comparatively simple. Following a routinely complete history and physical (including neurological) examination, to exclude well-recognized disease, the following observations are repeated before and after performing the exercise: pulse rate, blood pressure, and reflexes, including Chvostek's and Hoffman's signs. Samples of urine are taken. The patient, then lying in a comfortable position without the inhibition of constricting clothing, is asked to breathe with the regulation of the hand of the examiner placed over the epigastrium. The lightest possible pressure is made, and the rhythm is initiated so that respirations occur at the rate of 18 to 20 per minute. The time-interval from the beginning of the test to the onset of symptoms is noted. Effort is made to induce a state of carpopedal spasm,¹² or a repetition of the symptoms of the chief complaint. If no reaction is obtained within 30 minutes, the procedure is discontinued. One should judge whether or not the patient is at ease. Some patients become slightly excited and do not breathe regularly, and the slight pause they unconsciously insert into the cycle is enough to maintain the normal acid-base balance. After the results are obtained, the patients are given carbon dioxide and oxygen inhalations (30 per cent CO₂ to 70 per cent O) to relieve the spasms or other symptoms. (Having the patient hold his breath or re-breathe into a paper bag may likewise clear off the symptoms promptly.) While this improvement is being accomplished, with the patient breathing at the same rate as before, the procedure is explained to the patient in non-technical language. Simple comparisons are made to demonstrate to him the mechanism involved, and conclusions are drawn illustrating to him his rôle in the production of his own symptoms, and to show how easily and

simply he may regain his former feeling of well-being. Should the patient not cooperate well, calcium chloride, 5 c c of a 10 per cent solution, may be given intravenously, and the reactions may be explained later when the patient is more quiet.

PROTOCOLS OF EXAMPLES OF SEVERAL TYPES OF THE ANXIETY STATES

Below are the histories of a group of patients, illustrating the various types of responses which follow the common prodromal symptoms. Typically, all of these patients give a story of an encounter with some difficulty which causes emotional stress and anxiety. There is palpitation and tachycardia, hyperpnea, and a feeling of great weakness and fatigue. Within a variable period, there follow paresthesias of the hands and feet, and isolated muscular contractions which are associated with pain or tension similar to the symptoms mentioned in the patient's chief complaint. The characteristic local responses of which the patient complains are repeated quite regularly in successive attacks.

GROUP I

Tetany

Case 1 D E, female, aged 24, separated (Case 6, Chart 1)

Chief complaint Spasms of the hands and feet, duration one month

Present illness Two years before entry the patient had experienced numbness in both hands, which had responded to intravenous iron medication. Six months prior to entry, while sitting in a theater, she found that she was unable to swallow because of stiffness of her throat muscles. Two months before entry she had severe headaches for which she again received intravenous iron therapy. At this time she started proceedings for a divorce. Shortly after, she experienced gaseous distention and diarrhea. She became worse following alkalization. One month prior to entry, while in her lawyer's office she noticed numbness of her hands and feet and a "puckering" sensation about her mouth. Later she had stiffness of the muscles of her hands and feet. Subsequent attacks progressed to the typical carpopedal spasm of tetany. Paresthesia of the skin of the chest-wall was noted. The patient stated that carbonated water alleviated these attacks.

Past history contributed nothing

Family history Her father, aged 49, and mother, aged 48, were living and well. They had been separated for years.

Marital history The patient had been married for four years. Her husband drank considerably. There had been recent separation, and divorce had been obtained.

Physical examination All findings were negative or within normal limits. The only pertinent observation was that the patient talked very hurriedly and took many deep breaths.

Neurologically, perception by senses was normal throughout. Muscles were equal and active in all movements. Reflexes were not hyperactive and were equal.

Laboratory tests Urine, stool and blood were within normal limits. Gastric analysis, absence of free HCl, but normal response to alcohol meal. Blood calcium, total 8.67 mg per cent, diffusible 4.62 mg per cent.

Hyperventilation exercise Trousseau's and Chvostek's signs, though negative at the start, became positive within 40 seconds. At four minutes, numbness of the

mouth and fingers with coolness of the knees occurred, at six minutes, stiffness of the mouth and adduction of the right thumb, at eight minutes, typical carpopedal spasm. Four minutes after inhalations of a mixture of O_2 (95 per cent) and CO_2 (5 per cent) were started, the patient returned to a normal state.

Psychiatric consultation revealed that the patient had considered herself an invalid after a doctor had told her that "she was not one of the 90 per cent who would get well."

Progress After the demonstration, the patient became convinced that the convulsions were due to her method of breathing. She was placed on a diet and given medication to increase calcium intake and to decrease the pH of the blood. Up to the present, four months after discharge, she has had no recurrence of attacks.

Case 2 A. H., female, aged 58, widow (Case 2, Chart 1)

Chief complaint Spasms of the hands and feet, duration one year

Present illness The patient first noticed symptoms while riding in an open car. She first felt irritated, then weak, then experienced numbness of her hands and later stiffness of the hands and feet. One year following her husband's death she collapsed in a theater. She had another seizure typical of tetany when she witnessed an automobile accident.

Past history Non-contributory except for information included under "Marital history."

Marital history The patient had been married at the age of 24, she had one son. As a family, they were affectionate. She and her husband were always told that they appeared very young, and she dressed accordingly. When her husband died, she realized that she was not young, and she felt, because her son was to be married, that she had little to live for.

Physical examination Findings were within normal limits. The overuse of cosmetics was obvious. Neurological examination showed hyperactive reflexes.

Laboratory tests Results were well within physiological limits. For report of blood-chemistry see chart 1.

Hyperventilation exercise At 16 minutes, band-like headache, at 18 minutes, patient felt weak, at 21 minutes, she had numbness of both hands, at 22 minutes, paresthesias were noticed, at 23 minutes, carpopedal spasm of both hands occurred. Chvostek's sign although negative before, became positive 3° bilaterally, the reflexes were markedly increased.

Course Within one month after entry, her depression regarding the death of her husband and fear for the future had disappeared. Two attacks started, but she was able to prevent spasms by holding her breath and "counting to ten." Within two months self-control had been completely regained.

Case 3 M. R., female, aged 21, single

Chief complaint Convulsive seizures, duration six weeks

Present illness The patient had periods of fatigability followed by irritability and then flushing of the face, chest and arms, terminating in headache. Seven weeks prior to entry she noticed that she had swollen eyelids and a distended abdomen. She sought medical advice and a vaginal examination was made in the course of the investigation, abdominal cramps followed this. She then noticed that her jaws became stiff, and that her hands and arms ached. The next day her hands and feet became stiff, and every day after that she had four or five such attacks, which were carpopedal spasms. Systems The patient had had insomnia, distention of the stomach, and nocturia once or twice nightly.

Physical examination Findings were normal, including neurological examination, save for slightly dilated pupils and hyperactive reflexes.

Laboratory tests and roentgen-ray examination Urine, blood and spinal fluid were normal Wassermann and Kolmer reactions were negative Encephalogram showed no abnormality Glucose tolerance test was within limits of normal Gastric analysis showed the following figures for free acid Fasting 90°, 1st specimen, 0°, 2nd, 20°, 3rd, 40°

Hyperventilation exercise reproduced her symptoms, and these were relieved by inhalations of CO₂

Follow-up report The patient returned after six weeks, at this time feeling well She was examined by an obstetrician who made a diagnosis of pregnancy, whereupon she had another attack of tetany from which she recovered When last seen she had been well for three months on an acid-ash diet and ammonium chloride

Comment This patient's condition was a rather typical example of hyperventilation tetany without other symptoms Her neurosis was initiated by the collapse of a romance because it conflicted with her almost mid-Victorian ideals of conduct The original cause has not been removed, but she is symptom-free because she knows how her symptoms are produced and can prevent them

Case 4 C C, female, aged 42, single (Case 3, Chart 1)

Chief complaint Muscular cramps of the hands and feet

Present illness The patient had a feeling of air-hunger accompanied by dyspnea, numbness of the hands and feet, and then spasms of the hands and feet similar to carpopedal spasms

Physical examination Findings were normal throughout, including activity of reflexes

Hyperventilation exercise reproduced her attacks, which were controlled by inhalations of carbon dioxide Ammonium chloride was of little value, the best results were obtained by conscious control of respiratory frequency

Remarks This case is introduced to show that some patients respond to one type of therapy when the usual methods fail This woman's neurosis was controlled without the aid of measures usually classified as psychotherapeutic

Case 5 N A, female, aged 17, single

Chief complaint Generalized eczema, malnutrition, and spasms of the hands and feet

Past history This girl had a definite family history of allergy, and over a period of years she had been suffering from intermittent attacks of an allergic dermatitis which had responded indifferently to local treatment She was subject to attacks of general malaise, cough, dyspnea, and pain in the chest accompanied by a sensation of air-hunger She hyperventilated and developed carpopedal spasms with paresthesias of the hands and feet

Physical examination Poorly developed and poorly nourished girl with crusted lesions over the neck and face Her condition was normal otherwise save for hyperactive reflexes

Laboratory tests The urine was acid The blood was normal Serum calcium 107 mg per cent Blood iodine No 60 (normal No 110) Basal metabolic rate 6 per cent minus She was found to be somewhat sensitive to cereals and to carrots

Hyperventilation exercise Tetany could be produced volitionally and controlled by holding her breath The patient was able to control, also, all other spasms by this method

Comment This patient is presented to illustrate two types of response of the autonomic nervous system the allergic manifestation, which is said to be of the parasympatheticotonic group, and the tetany, which is thought to be a sympatheticotonic response Her neurosis was thought to be due to restrictions of her social life

because of her long standing skin disease The cause of the neurosis was not removed completely, but abatement of the skin lesions through treatment helped considerably

GROUP II

Evidence of Generalized Muscular Irritability without Actual Tetany

Case 6 B K, female, aged 40, married

Chief complaint Headache over the right orbit

Present illness At times this headache was likewise felt over the entire right side of the head She had nervousness and irritability which were made worse by the taking of citrate of magnesia for chronic constipation These symptoms were aggravated by visits to her mother-in-law

Physical examination Negative throughout save for hyperactive reflexes and 1° Chvostek's sign

Laboratory tests The urine was alkaline The blood was normal Gastric analysis showed absence of free acid in the fasting specimen and following an alcohol test-meal, and 46° after administration of histamine The basal metabolic rate was 15.4 per cent minus

Progress The patient's symptoms were controlled by medical therapy but at no time were there more alarming symptoms than those mentioned in the "present illness" It was felt that if medical therapy had not been instituted she would have progressed to a convulsive state

Case 7 L S, female, aged 53, married

Chief complaint Nervousness and irritability for seven years

Present illness After menopause and its symptoms had disappeared, this woman had a severe injury to her hand which occurred on the day of her mother's funeral Since that time she had suffered a feeling of impotence and weakness, with trembling and profuse sweating

Physical examination Restless patient, with hyperactive reflexes Blood pressure 176 systolic and 110 diastolic Normal intercourse had been impossible because of sclerosed hymen

Laboratory tests Urine and blood were normal Gastric analyses showed free acid to be absent after administration of alcohol and histamine

Hyperventilation exercise caused merely irritability and trembling, there were no symptoms of spasm

Progress This woman improved following the use of dilute hydrochloric acid with her meals, and sodium acid phosphate 0.3 gm, three times daily

GROUP III

Severe Convulsive State Simulating Grand Mal

Case 8 H B, male, aged 27, married (Case 11, Chart 1)

Chief complaint Convulsions during past eight years

Present illness While painting his car, the patient fell unconscious and remained so for nearly 45 minutes On recovery he felt weak and stiff There is no history of incontinence of urine or stool The patient had had no injuries During any excitement or following any argument, these attacks recurred As described by his wife, during attacks the patient became pale and fell to the ground with generalized tonic and clonic convulsions These episodes had no apparent resemblance to carpopedal spasm The patient had similar attacks at night In recent years he has injured his mouth in these spasms

Past history The patient was a coffin-maker He had been married for the second time, his wife was frigid

Physical examination Thin, asthenic male who appeared to be younger than stated age. The findings were normal save for Chvostek's sign of 1° on the right and 2° on the left.

Hyperventilation exercise At 5 minutes, numbness of hands and feet, at 9 minutes, adduction of the right thumb, at 11 minutes, carpopedal spasm, at 13 minutes, generalized tonic and clonic convulsions with spasm of the masseter muscles. There was no incontinence.

Laboratory tests Negative throughout save as shown in chart 1.

Progress The convulsions were not controlled until he was placed on an acid-ash regime, with calcium and parathormone. It was noted on his return visits that the time-interval between attacks became greater and the degree of response to the hyperventilation was much less.

Case 9 M L, female, aged 29, married

Chief complaint Convulsions, duration 9 months

Present illness Generalized muscular irritability preceded the onset of tonic spasm with opisthotonus. There followed clenching of the fists with kicking of the feet. Next, precordial pain occurred, with radiation down the right arm. The patient never injured herself, and had no incontinence. The seizures occurred every 4 to 6 weeks, and usually followed altercations with the family.

Physical examination Reflexes hyperactive, otherwise negative.

Laboratory tests Examinations of urine, blood, stool, and spinal fluid, and gastric analysis were negative. Basal metabolic rate 67 per cent minus. Roentgen-ray examination showed no evidence of an intracranial lesion.

Hyperventilation exercise produced trembling, dizziness and a feeling of faintness, and reproduced the tonic state described above which was not a form of tetany. Her husband said that this response was the same as that which occurred in her attacks. Before hyperventilation, examination of urine by Folin titration method showed 150° (c c 0.1 normal NaOH), and after hyperventilation, 36°, which indicates a definite shift to the alkaline side.

Comment This patient, although in a general convulsive state, has a history which suggests hysteria. She improved after developing self-control of this mechanism, and has had many less seizures.

GROUP IV

Localized Spasms of Muscles, with Symptoms Simulating Those of Cardiovascular Disease

Case 10 F S, female, aged 27, married (Case 10, Chart 1)

Chief complaint Precordial pain for 1½ years

Present illness This patient suffered weakness, easy fatigability and twitching of the muscles of the body for a short time prior to the onset of the chief complaint. She then noticed severe pain over the precordium, which radiated down the left arm. There was no dyspnea until later, but she had nausea and eructation. Just before entry a right occipital headache developed with some photophobia.

Physical examination Thin, nervous woman who cried easily. She appeared to be of the stated age. Her heart was not enlarged, sinus arrhythmia was present, there were no murmurs. Blood pressure systolic 110, diastolic 80. Reflexes were hyperactive. Chvostek's sign was 1° on both sides.

Laboratory tests Blood and urine were normal. Tuberculin test was negative. Phenolsulphonephthalein test total 60 per cent. Mosenthal test showed no fixation and good concentration. Electrocardiogram showed evidence of sinus arrhythmia and T-waves diphasic in Leads I and II, inverted in Lead III.

Hyperventilation test At three minutes, tachycardia, at eight minutes, hysterical crying, at eleven minutes, stiff lips and numbness of hands, at 15 minutes, adduction of the left thumb, at 17 minutes, carpopedal spasm, and pain recurring over the heart. See chart 1 for reports of blood and urine chemistry.

Comment This patient's neurosis was based on fear. Her brother-in-law had killed his wife and his wife's family. The patient feared that her husband would do the same. The combination of psychic purgation and the use of ammonium chloride were sufficient to control symptoms of the complaint for three months.

Case 11 J. A., female, aged 32, married (Case 4, Chart 1)

Chief complaint Precordial pain for two years

Present illness The patient had onset of acute pain over the precordium, felt particularly on effort. There was radiation of the pain to the left scapula. Attacks of diarrhea followed these bouts of pain, which occurred also when the patient was present at public gatherings and after she drank alcoholic beverages. Before entry she noticed stiffness of the hands and feet without actual spasms of the muscles.

Physical examination Negative throughout except for the hyperactive reflexes and a positive Chvostek's sign bilaterally.

Laboratory tests See chart 1 for all positive findings. Stools were negative for organisms and parasites which cause diarrhea.

Hyperventilation exercise At the end of 21 minutes there was a reproduction of the symptoms of pain in the region of the scapula and precordium, also of the numbness and stiffness of which she had complained. The Chvostek's sign was 3° bilaterally.

Comment This patient's neurosis was founded in dislike of her father-in-law. She was led to understand the source of her symptoms, and to be able to control them through regulation of her respiratory rate. She was placed on the acid-ash regime. Her symptoms disappeared and did not recur. The cause of this patient's neurosis could not be removed.

Case 12 D. G., female, aged 35, married (Case 13, Chart 1)

Chief complaint Rapid heart rate and precordial pain

Present illness This patient noticed that after emotional upsets and altercations, she was unable to inspire enough air for her need. Later she had onset of severe and persistent tachycardia without palpitation. A distressing tension was felt about her heart without actual pain.

Physical examination Reflexes were hyperactive, Chvostek's and Trousseau's signs were negative.

Laboratory tests For the positive findings, see chart 1.

Hyperventilation exercise At three minutes, dryness of the mouth, at five minutes, stiffness of the hands and feet, at 10 minutes, diaphragmatic constriction with momentary pain under the left breast simulating the chief complaint. Hoffmann's, Chvostek's and Trousseau's signs remained negative.

Comment As the cause of this patient's neurosis was never discovered, it is doubtful that permanent cure was effected. However, at her last visit, she had been symptom free for one month.

Case 13 M. M., female, aged 36, divorced (Case 15, Chart 1)

Chief complaint Palpitation and precordial pain, duration one year

Present illness Following the nursing of her mother through a fatal attack of angina pectoris, this woman had insomnia for three weeks and lost 16 lbs. in weight. She suffered an attack of palpitation which was mitigated by quimidine. She developed pain over the precordium pressure-like in character, which radiated to her left elbow.

Physical examination The patient had the physical signs of rheumatic heart disease with mitral stenosis and insufficiency

Laboratory tests Results are recorded in chart 1. Electrocardiogram showed evidence of delayed A-V conduction, slurred Q-R-S complexes and upright T-wave in Lead IV

Hyperventilation exercise produced rapid heart-rate in addition to the symptoms of the chief complaint

Comment This case shows that a neurosis may overlie organic disease, making it difficult to evaluate the symptoms of the organic lesion. However, the patient clinically did not have the type of heart lesion that would be expected to give rise to the symptoms of which she complained. In such instances the patient, even though symptom-free, should be kept under observation in order to follow the progress of the organic disease

Case 14 M M, female, aged 23, married (Case 16, Chart 1)

Chief complaint Rapid pulse and pain over heart

Present illness Following the death of her father, this woman became irritable, but it was not until after the birth of her child that she noticed rapid heart rate and pain over her heart experienced on effort. She had dyspnea on exertion. The pain did not radiate to her arms or neck. She did not have the symptoms of irritability that had bothered her at first

Physical examination Negative save that the patient was very nervous and was observed to sigh frequently during the course of the examination

Laboratory tests See chart 1 for changes after hyperventilation. Free acid was low in the gastric content (between 4° and 8° even after injection of histamine)

Progress The patient's recovery was more protracted than that of most patients, administration three times a day of 8 gm of ammonium chloride after meals and hydrochloric acid 1 cc with each meal were required. After two months on this regime she had no tachycardia and only occasional episodes of hyperventilation

Case 15 T W, female, aged 35, widowed

Chief complaint Palpitation

Present illness Following the injection of novocaine for some dental work the patient had a hysterical attack of crying which ended in a tetanoid spasm accompanied by paresthesias. Her father died from coronary occlusion, and throughout his illness the patient nursed him. Shortly thereafter, she became subject to pain over the precordium which did not radiate to the arms but which was associated with the symptoms of fatigue, paresthesias and stiffness of the extremities. These attacks occurred when she was emotionally distressed, particularly about finances and about her health

Physical examination The patient had a splenomegaly, the cause of which was not discovered, she had hyperactive reflexes and a 1° Chvostek's sign

Laboratory tests Essentially normal results were obtained throughout

Hyperventilation exercise produced the typical carpopedal spasm after 38 breaths were taken. The symptoms of the chief complaint were reproduced. These were relieved when the patient held her breath. Exercise for determination of cardiac efficiency produced the same symptoms

Comment This patient is another illustration of the hyperirritable individual who assumes the symptoms of the illness of a person with whom he has had intimate contact. It is felt that these symptoms are not imagined, but are really manifestations of local spasms of the intercostal muscles and possibly of the diaphragm

GROUP V

Vascular Disturbances Pseudo-Raynaud's Disease

Case 16 M T, female, aged 54, widowed

Chief complaint Numbness of the hands

Present illness This woman had had considerable difficulty with her husband and had been separated from him before he died. She suffered from irritability, faintness, easy fatigability, and paresthesias of the hands. Later she noticed that when she was excited, the fingers of both hands became blanched in corresponding areas. These changes occurred likewise on exposure to the cold. Still later she began to have a feeling of air-hunger and a choking sensation in the throat.

Past history In 1924 this patient had a sub-total thyroidectomy for Graves' disease. At that time she had positive eye-signs, an enlarged thyroid gland with a bruit, and basal metabolic rates of 59.5 and 22.9 per cent respectively on two occasions. At operation she was found to have a thyroiditis. In September 1927, her basal metabolic rate was 7.5 per cent minus.

Physical examination The patient had nothing about the hands which suggested capillary instability. Her reflexes were active.

Laboratory tests Negative save that gastric analyses showed no free acid in the fasting contents and only 8° after histamine was administered.

Hyperventilation exercise reproduced the blanching of the fingers bilaterally in corresponding positions, the areas increasing with the degree of hyperventilation. The same reaction was produced by immersing the hands in cold water.

Comment This patient apparently illustrates the spasm of vessels to a marked degree. The reaction did not cause a true tetany but only a stiffness of the hands. She was placed on NaCl, 1 gm. three times a day and HCl given by mouth, and her vascular disturbances have decreased considerably although they have not as yet entirely disappeared. We have observed several patients in the clinic who presented local blanching and cyanosis of the fingers (Raynaud's syndrome) whose local symptoms cleared promptly upon holding the breath or breathing CO₂.

GROUP VI

Disturbances Simulating Diseases of the Chest, Mainly of the Asthmatic Type

Case 17 C D, female, aged 55, married (Case 14, Chart 1)

Chief complaint This woman had a sense of choking and suffocation at the onset of her menstrual periods. No other symptoms occurred until she was 45 years of age when she suffered pain down her arm and paroxysmal dyspnea. She was observed at this time and has been examined frequently since for angina and more recently for coronary disease. No definite evidence has been found of the existence of coronary disease. These symptoms became worse when she had to care for her paralyzed husband whom she did not love and who was 20 years older than herself. She suffered extreme weakness and easy fatigability and had a sensation of clutching compression of the throat which would cause her to gasp for air. She had pain down the left arm during severe seizures.

Physical examination showed hyperactive reflexes. The cardiac findings were within normal limits.

Laboratory tests See chart 1 for reports of chemical tests on the urine and blood. Basal metabolic rate 32.6 per cent minus. Electrocardiogram showed left axis deviation and flat T-waves.

Hyperventilation exercise At 60 seconds there was fixation of the diaphragm, at 80 seconds, cyanosis of the nose and fingers, at 90 seconds, marked spasm of the bronchial and tracheal muscles, with a generalized convulsive spasm of the bronchial

and tracheal muscles, with a generalized convulsive seizure in an effort to regain breath. During the process she developed a 2° Chvostek's sign. Trousseau's sign remained negative.

Comment As well as being an excellent example of simulated asthma, this patient was remarkable because of the exact regularity of the cycle of her reactions. One could predict within the second what type of response would occur. She recovered rapidly following inhalations of CO₂, and has remained without major symptoms on an acid-ash regime.

Case 18 M H, female, aged 45, separated

Present illness The patient had symptoms of fatigue and weakness, paresthesias, and stiffness of the hands and feet. She came to the Clinic with the complaint of a sensation of constriction in the neck, and a lump was noticed there. She was thought to have thyrotoxicosis. Constriction of her throat caused considerable dyspnea and attacks similar to those of asthma.

Physical examination A small nodule was found at the left lower pole of the thyroid. There were no signs of toxicity, however.

Laboratory tests Urine and blood were normal. Basal metabolic rate 64 per cent minus. Gastric analysis 17° free acid in the fasting specimen, with normal response to instillation of alcohol.

Hyperventilation exercise produced paresthesias of the hands, increase of reflexes and a sensation of constriction of the throat.

Progress No observations were recorded as to the results of therapy. This patient was less troubled by her symptoms than was the patient described above (Case 17).

Case 19 J B, male, aged 46, married

Chief complaint Dyspnea

Present illness This man had epigastric pain simulating that of ulcer of the duodenum, and he had been treated with alkalis for years. He became a morphine addict, and he contracted syphilis. Because of fear of his disease he became irritable and had dyspnea on exertion. Later he began to have a tense feeling in his throat. He had constipation because of his morphine addiction.

Physical examination Findings were normal in every respect.

Laboratory tests Urine was alkaline. Blood was normal. Spinal fluid examination was negative. Roentgen-ray examination. Gastrointestinal series was negative. Gastric analysis. Normal amount of acid.

Ventilation was observed and the symptoms were seen to increase in the process. A formal experiment was not performed.

Progress Response to treatment was not rapid here because of the morphinism. Some improvement was noted after reassurance was given, as well as after the use of the acid-ash regime.

GROUP VII

Simulation of Thyrotoxicosis

Case 20 L J, male, aged 25, single

Chief complaint Numbness of the hands

Present illness For two years the patient had experienced nervousness, tachycardia and palpitation. He was easily fatigued. His basal metabolic rate was 14 per cent plus, and a subtotal thyroidectomy was performed. Following this operation, symptoms of tachycardia and palpitation decreased but the paresthesias of the hands persisted.

Physical examination Asthenic male with hyperactive reflexes

Laboratory tests Blood and urine were normal Gastric analysis showed an absence of free acid even after injection of histamine Basal metabolic rate, 34 per cent minus

Hyperventilation exercise reproduced the symptoms of the hyperthyroidism and the paresthesias of the hands

Progress The patient was placed on a high salt intake and improved slightly He was then given HCl by mouth

Comment This man and others of this group are examples of a type of patient appearing in the thyroid clinic who is not thyrotoxic but who has a neurosis giving similar symptoms

Case 21 M M, female, aged 37, married

Chief complaint Nervousness following an operation

Present illness The patient had been nervous for the past five years She had tremor, intolerance to heat, increased appetite, and a loss of 10 lbs in weight She noticed a sudden enlargement of the left side of her neck, and visited a doctor At this time she had dyspnea on exertion and nocturia On examination the left lobe of the thyroid was found to be enlarged The basal metabolic rate was 44 per cent plus An adenoma of the thyroid with hemorrhage was diagnosed, and was found when thyroidectomy was performed Six months later the patient returned to the clinic Save for the absence of the swelling, she had at this time the same symptoms that she had had at previous entry

Physical examination was negative

Laboratory tests Gastric analysis showed absence of free acid, but a normal response to alcohol test-meal

Hyperventilation exercise reproduced all of her symptoms

Progress This patient improved greatly following the use of ammonium chloride and the institution of an acid-ash diet Her symptoms are now controlled The neurosis was not cured because it was caused by the marital status which has remained unchanged

Case 22 L F, female, aged 25, married

Chief complaint Nervousness and fullness in the neck

Present illness For six years this woman had noticed increasing irritability There were tremor and nervousness, palpitation, tachycardia and intolerance to heat On several occasions she had hysterical upsets

Physical examination showed an adenoma of the thyroid The basal metabolic rate was 18.6 per cent plus Radiation with roentgen-ray was begun, and two months later the basal metabolic rate was 8.5 per cent minus After four years she returned with the same symptoms It was learned that, while she was living at her uncle's home, she had a clandestine romance with him which she was unwilling to stop, and which was in constant danger of exposure

Laboratory findings were within normal limits

Hyperventilation exercise reproduced all of the symptoms of the present illness

Progress At the present time she has shown improvement under medical therapy Psychotherapy is being directed toward helping her to establish some sort of decision as to her relationships in the future This patient was not operated on, as were the former patients, but it is believed that her adenoma is not toxic

Case 23 E H, female, aged 29, married

Chief complaint Nervousness for four years

Present illness Four years ago the patient began to notice a feeling of weakness

and increasing nervousness. She had loss of emotional control. During the next year an enlargement appeared in her neck and she noticed that her heart rate was rapid and that she had increased perspiration. Treatment with Lugol's solution caused improvement. One year before entry she returned to the clinic with palpitation and dizziness. She had lost four lbs. She had dyspnea and a sense of tension in the chest on inspiration.

Physical examination There was slight enlargement of the right lobe of the thyroid. She seemed to be more nervous than the signs of thyrotoxicosis would warrant.

Laboratory findings were entirely normal.

Hyperventilation exercise reproduced the symptoms of palpitation and dizziness and the sensation of constriction in the chest.

Comment The results of treatment cannot well be evaluated here because of an involved social history which has not been completely obtained. The exercise aided in establishing a contact with the patient which has been very helpful in psychotherapy.

GROUP VIII

Gastrointestinal Disturbances

Case 24 F H, male, aged 35, single (Case 12, Chart 1)

Chief complaint Epigastric pain

Present illness This man suffered severe weakness and nervousness and muscular twitchings. He developed midepigastric pain followed by gas pains, at first occurring after meals and later having no relation at all to meals.

Physical examination Hyperactive reflexes and 1° Chvostek's sign were found.

Laboratory tests See chart 1 for urine and blood findings.

Hyperventilation exercise produced the muscular twitchings in six minutes and generalized muscular contractions in nine minutes.

Progress This man's symptoms were relieved by the acid-ash regime which of course is directly opposed to the usual method of treating peptic ulcer.

Case 25 W R, male, aged 27, single (Case 17, Chart 1)

Chief complaint Epigastric pain relieved by food

Present illness The patient's pain occurred in the epigastrium before meals and was relieved by food and soda. The pain radiated to the back under the left scapula. There was no nausea and no vomiting or melena. This man also suffered a sense of suffocation and tightening of the facial muscles when he talked or laughed too much.

Physical examination Perspiring, nervous and asthenic male appearing to be of the stated age. Reflexes hyperactive and equal.

Laboratory tests All findings were normal save that the gastric analysis showed no free acid and only 22° after injection of histamine. Gall-bladder visualization was negative. See chart 1 for reports of the blood and urine chemistry.

Hyperventilation exercise reproduced the epigastric pain and produced carpo-pedal spasm. Chvostek's sign 2° was observed bilaterally.

Comment This patient had obvious signs of tetany but associated with it were the symptoms of the complaint. He had suffered from atrophic arthritis and it was felt that his discouragement over the progress of this disease was the basis of his neurosis.

Case 26 R S, female, aged 45, married

Chief complaint Eructations of gas from the stomach

Present illness Since the age of 18 the patient has had gas pains for which she had taken soda and at intervals she has had periods of dizziness. Ten years before

entry, following an operation for tonsillectomy she had a recurrence of the spells of dizziness. For two years she is said to have had tarry stools following these attacks.

Physical examination Entirely negative

Laboratory tests Urine, blood and stool were normal. Gastric analysis. No free acid after instillation of alcohol, but 62° after injection of histamine. Roentgen-ray examination. Gastrointestinal series and barium enema were negative.

Hyperventilation exercise produced diaphragmatic spasm, belching and hiccoughing. This patient demonstrated fixation of the diaphragm more typically than most patients, and she had symptoms of her chief complaint at the same time.

Case 27 R S, male, aged 40, married

Chief complaint Tenderness in the epigastrium

Present illness The patient had epigastric pain first 10 years before entry, and his attending physician diagnosed peptic ulcer. The Sippy diet relieved his symptoms. Three months prior to observation he had recurrence of symptoms, and at this time a gastrointestinal series gave findings interpreted as duodenitis without gastric retention. He remained on the Sippy regime for three months and then began to have cramps in his legs, tightening of the muscles of his face and paresthesias of his hands. These symptoms happened under emotional strain.

Physical examination Thin, asthenic male who appeared to be of the stated age. Hyperactive reflexes and 1° Chvostek's sign were found.

Hyperventilation exercise reproduced the symptoms of tetany. The patient was placed on ammonium chloride 0.6 gm three times daily. He recovered from these symptoms, but in three months' time the symptoms of ulcer appeared. A neutral powder was then used so that the acid-base balance could be more finely adjusted.

Comment It was felt that this man was on the verge of alkalosis tetany and in excitement mild over-ventilation caused the tetany to occur.

Case 28 J C, female, aged 34, married (Case 1, Chart 1)

Chief complaint Irritational distress in the epigastrium, duration 1½ years

Present illness This patient, a teacher, always had symptoms following the close of the school term. At these times she had epigastric distress, easy fatigability, headache, and paresthesias of the hands.

Physical examination Negative except for hyperactive reflexes and Chvostek's sign 1° bilaterally.

Laboratory tests The urine was alkaline, the blood was normal. See chart 1 for report of urine and blood chemistry.

Hyperventilation exercise produced headache, trembling of the arms and clonus, within nine minutes.

Progress This patient improved markedly after acid therapy was instituted. Her neurosis was initiated by a marital problem which was later solved to some extent by her loss of symptoms and by an explanation of the problem.

Case 29 T P, female, aged 31, married

Chief complaint Eructations of gas from stomach, and mucous colitis

Present illness For four years this woman had had increasing nervousness and irritability, and then she had midepigastria distress with eructation and nausea. Colitis with diarrhea developed and she expelled quantities of mucus.

Physical examination A thin, poorly nourished, asthenic woman who talked so fast and inspired so rapidly that during the taking of her history she produced the symptoms of her complaint.

Laboratory tests Normal findings for urine and blood. Gastric analysis. Absence of free acid in the fasting specimen and 32° after injection of histamine. Be-

fore hyperventilation, the urine tests by the Folin titration method showed 960°, and after hyperventilation 36°, which is evidence of a complete shift to "actual alkalosis"

Progress This patient responded well to therapy directed toward production of mild acidosis. Her neurosis was based on the fear of losing her husband because of her chronic illness. This neurosis decreased with her improvement.

GROUP IX

Simulation of Diseases of the Special Senses

(Pseudo-Memere's Syndrome)

Case 30 T M, male, aged 26, single (Case 9, Chart 1)

Chief complaint Vertigo

Present illness This man had a sudden onset of dizziness and tinnitus with apparent loss of hearing in one ear, sometimes noticed on the left side, sometimes on the right. He noticed, also, a numbness of the hands with rigidity of the muscles.

Physical examination The patient was of the pyknic type. At first the findings were normal save for hemorrhoids which were removed under general anesthesia. On return from surgery, he was in severe tetany with marked nystagmus, and while he was being revived by inhalations of CO₂ and injections of calcium chloride he again complained of tinnitus and deafness.

Laboratory tests See chart 1 for findings.

Hyperventilation exercise reproduced in 12 minutes the symptoms mentioned above.

Progress This man was placed on ammonium chloride, 0.6 gm three times daily. When he was seen three months later, it was noticed that the exercise produced the symptoms after a longer interval from initiation of the breathing, and that the symptoms were not so profound. Later, after this man was married, his symptoms did not recur even when he was allowed a normal diet and when medication was withdrawn. Since this man was not the asthenic type, the true nature of his disturbance was not suspected until the symptoms occurred following the anesthesia. Other examples of this type of functional disturbance have been observed, and those patients have responded to the same measures.

GROUP X

Organic Disease (Coronary Occlusion) Producing Hyperventilation Tetany as a Symptom

Case 31 M McM, female, aged 50, married

Chief complaint Spasms of the hands with hyperpnea

Present illness Patient had increasing fatigability and numbness of one hand and arm. Later, she had pain across the precordium. She had no dyspnea, orthopnea, palpitation or tachycardia. She began to have abdominal distention but did not have nausea or vomiting.

Physical examination Heart was not enlarged to percussion. Sounds were very faint, they were regular and no murmurs were heard. Lungs were clear. Liver and spleen were not palpable. There was no edema.

Laboratory tests Urine and blood were normal. The electrocardiogram showed left ventricular preponderance, diphasic T₁, slurred QRS, notched R_s, diphasic T₂, positive S-T₁, negative S-T₂.

Course The day of entry she had an attack of distention, became slightly cyanotic, and had a definite carpopedal spasm. There was neither pain nor dyspnea. She was held to hold her breath, and without any medication the attack wore off quickly. The next morning she had another attack in which she died.

Comment We mention this patient as an interesting example of the superposition of this syndrome on the symptoms of serious organic disease. This case in itself is a warning of the constant danger of classing too many patients as neurotic, and of the need for thorough physical proof to rule out organic illness before it is concluded that the patient's condition is merely a neurosis.

GROUP XI

Suspected Neuroses Which Were Not Proved by Hyperventilation Experiment

Case 32 L P, female, aged 45, married (Case 5, Chart 1)

Chief complaint Pain over precordium

Present illness This patient had attacks of weakness and dizziness which occurred at increasingly frequent intervals up to the time of entry into the hospital. Several months before, she had become conscious of pain over the precordium which did not radiate to the arms but which was associated with dyspnea and palpitation.

Physical examination Sinus tachycardia was present. There was no evidence of myocardial damage.

Laboratory tests Normal findings for urine and blood. Electrocardiogram, and roentgen-ray film of the chest for determination of the size of the heart, were negative. See chart 1 for reports of laboratory work after hyperventilation.

Hyperventilation exercise failed to induce the symptoms of the complaint, nor were symptoms of tetany produced. The CO combining power was about the same as that found in other instances. She was placed on an acid-ash regime and improved as well as had other patients. It is probable that she was not exercised long enough to produce the desired results. Her neurosis was based on economic problems which were not solved.

Case 33 A A, female, aged 43, single (Case 7, Chart 1)

Chief complaint Precordial pain

Present illness Following the loss of her family, this woman had nervous irritability. Later she had pain in the left side of the chest, not radiating and not associated with dyspnea.

Physical examination Negative

Laboratory tests, including electrocardiogram, roentgen-ray studies of the chest and spine. No abnormal findings.

Case 34 R McA, female, aged 40, single (Case 8, Chart 1)

Chief complaint Hoarseness, duration 6 weeks

Present illness For 7½ years this woman had had pain in the tips of the fingers with skin lesions of a desquamating erythematous nature. She had also had numbness and stiffness of the fingers. She had had attacks of nausea and vomiting.

Physical examination Skin lesions were present which are described above. Reflexes were hyperactive.

Laboratory tests Urine and blood were normal. Electrocardiogram showed evidence of myocardial damage. Sedimentation rate 35 minutes. No evidence of arterial disease was obtained by surface temperature readings before and after administration of spinal anesthesia. Response to alcohol meal was normal.

Hyperventilation exercise did not produce the desired results because of poor cooperation on the part of the patient on the several occasions when it was tried. It will be noticed that the CO₂ combining power increased, and this may be evidence that the patient became less sensitive to nervous stimulation.

Case 35 C M, female, aged 51, widowed

Chief complaint Dyspnea, duration five years

Present illness Following the onset of irritability, this patient had dyspnea, and then precordial pain which was non-radiating in character

Physical examination Slight peripheral arteriosclerosis was present The heart was not enlarged, a soft systolic murmur was heard at the apex

Laboratory tests Gastric analysis No free hydrochloric acid even after injection of histamine Electrocardiogram showed no evidence of cardiac damage Roentgen-rays of the chest and gall-bladder were negative

Hyperventilation exercise was not successful in producing the symptoms, chiefly because of inability to gain proper cooperation from the patient She signed her release from the hospital before further studies could be made

Comment The patients of this group are presented to illustrate that the hyperventilation exercise, to be successful, must be performed when the patient is completely at ease and understands that cooperation is essential for the success of the experiment It is possible that there are patients who will not react to the experiment even though they do cooperate These may have other mechanisms which produce their neuroses or they may have organic disease, the symptoms of which are not affected by the irritating action of the hyperventilation exercise

In table 1 are compiled the results of chemical studies on the urine and blood made before and after the exercise of hyperventilation

It is to be noted that in only 10 of the 14 patients listed is the carbon dioxide combining-power shown to be reduced, as described by McCance and others^{2, 8, 11, 18} In all save two, the chlorides are increased¹³ The total calcium is normal, but in some instances the diffusible fraction is at the lower limits of normal It may be that for these individuals, the diffusible calcium is actually below their normal threshold Blood-sugar and serum-proteins are normal, but near the lower limits Magnesium studies show normal determinations for most of the patients In those in which the serum magnesium is low, the magnesium content of red blood cells offsets the effect of the loss of serum magnesium as a cause of tetany¹⁴ The most clearly demonstrable shift of pH is seen in the studies of the urine, in which the colorimetric readings show an increase of from 2 to 3 units Likewise the drop in the ammonia per cubic centimeter is nearly 50 per cent Acetone was found in only one of the specimens taken It is felt that these results show a definite tendency towards alkalosis, and that the amount is that stated by Collip² to result in tetany Because of the expense entailed in the complete analysis as given above, it was thought advisable to use a test which would demonstrate this change most simply and graphically The Folin¹⁵ pH titration method for urine may be used with good results This procedure may be accomplished with the aid of the apparatus used in titrating gastric contents With the addition of 15 to 20 gm of potassium oxalate to 25 cc of urine, the titration is made with 0.1N sodium hydroxide, using phenolphthalein as indicator The specimens taken before and after the hyperventilation experiment are so tested, and are arbitrarily considered as being part of a normal output of 1,500 cc This step is made to take advantage of the normal figures as described by Folin, which

are 200 to 500° 0.1/N sodium hydroxide for that amount Folin states that any figure under 250 is a good indication of actual alkalinity So far, this test has proved satisfactory in that it shows a definite shift to "actual alkalinity"

Some explanation should be made for the almost insignificant changes in the figures which represent the shift in acid-base balance In subsequent publications, Dr Mayo H Soley of our clinic and Dr N W Shock of the Department of Biochemistry are to report the results of biochemical studies on similar patients, made in an attempt to gain more accurate data upon the rapidly changing shifts in the acid-base equilibrium and the gaseous exchanges through the lungs They have found that the shift in pH of the blood is greater than has been indicated in the past, and that the reaction is a rapid one They suggest that the indefinite results heretofore obtained are caused by the ungainly technic of venipuncture The general trend of their results supports the contention that there is a definite alkalosis present when hyperventilation takes place

In reviewing the histories of 50 patients, listed since 1928, in which the diagnosis of psychoneurosis with anxiety neurosis was made, figures were compiled which are shown in table 2 From the description of the

TABLE II

Since 1928, fifty patients have been admitted to the University of California Hospital whose conditions have been diagnosed as psychoneurosis with anxiety neurosis

| | |
|--|----|
| No of patients with symptoms similar to the ones now described as associated with hyperventilation | 36 |
| No of patients without these symptoms | 14 |
| No of patients with the following symptoms | |
| Weakness and fatigability | 18 |
| Numbness and paresthesia | 14 |
| Palpitation and increased cardiac rate | 12 |
| Dizziness | 10 |
| Nausea and vomiting | 4 |
| Muscular contractions | |
| Twitching, trembling, convulsive states | 14 |
| Tetany (not on basis of hypoparathyroidism) | 9 |
| Difficulty in swallowing, talking, breathing (pharyngeal-laryngeal spasm) | 8 |
| Precordial pain (intercostal muscle and diaphragmatic spasm) | 4 |
| Dyspnea (diaphragmatic spasm) | 14 |
| Epigastric pain (diaphragmatic spasm) | 2 |
| Constipation (spastic colon) | 5 |

The figures given above are compiled from the descriptions of the symptoms and signs that are given, and not from the results of formal experimentation

symptoms and signs alone, nearly 70 per cent of the patients classed as psychoneurotic were found to have symptoms of hyperventilation tetany, either local or general

DISCUSSION

In attempting to show the mechanism which is responsible for this sequence of events, we have constructed a diagram illustrating the physiological and biochemical changes which apparently form the background of

The chief response is through the sympathetic nervous system, the reaction of the parasympathetic system is less apparent¹⁶ Through the sympathetic system there is stimulation of the peripheral vascular bed, with spasm of the arterioles, and through impediment of the circulation a tissue anoxemia is produced which, according to Davies, Haldane and Kennaway,¹⁷ causes increased muscular irritability, and thus increases the peripheral sensations These authors have shown that this type of tetany can be relieved by oxygen inhalations Bazett and Haldane¹⁸ found that the hyperpnea due to hot baths can be relieved by a mixture containing 14.2 per cent oxygen and 8.5 per cent carbon dioxide Hill and Flack¹⁹ demonstrated that the hyperventilation of oxygen would not cause convulsions even when the alveolar carbon dioxide was reduced to 1.47 volumes per cent Certainly tissue anoxemia is an exciting factor in the production of muscular irritability, and thereby it can produce tetany

The stimulation of the members of the endocrine system is the second mechanism set in motion by the impulses coming in over the sympathetic nervous system Stimulation of the pituitary gland has, for its chief effect, the reactions which follow increase in water retention by the tissues, with subsequent storage of sodium ions and production of alkalosis and tissue hydremia The work of Furstenburg,²⁰ and, in an earlier period, of McQuarrie,²¹ is mentioned here because of the low total protein and serum albumin which was found in all but one of the patients listed This may be an indication of increase in hydremia, and if so there might be an increase in alkalosis through the presence of sodium ions

The best known effect of the sympathetic stimulation upon the endocrine system is that of the adrenals This stimulation, and the increase in the flow of adrenalin through the system, directly affects the substance of the nerves According to Bonnet, Franck and Richard,²² there is an increase in the summation of impulses, but no effect on the chronaxie of the nerve With repeated stimulation, smaller impulses cause the discharge of the cycle of symptoms grouped as the complaints of these patients Adrenalin is, of course, a cerebral cortical stimulant as well as a respiratory and cardiac accelerator by central action

The stimulation from hyperventilation is most likely central in origin Although no reports were found of studies in which adrenalin had been used, the work of Hammouda²³ throws some light on the question This investigator found that, when he used heat as a stimulus, he was unable to produce panting in dogs by its application to any of the peripheral sensory endings in the rib-cage or its viscera The only central nervous area that responded was the optic thalamus Whether adrenalin acts at this point is, at present, a matter of conjecture

A number of physiologists have studied hyperventilation in man From the work of Collip and Backus,² McCann,⁵ Grant and Goldman,³ and from the observations reported in this paper, it is felt that the mechanism centers

chiefly in the $\frac{\text{HCO}_3}{\text{NaHCO}_3}$ buffer and its variations with the exhalation of carbon dioxide from the lungs. With this change, NaHCO_3 is left in the blood stream. This base is usually eliminated through the kidney, but the process is not fast enough to prevent some of it from being deposited in the muscle. In an effort to maintain the acid-base equilibrium, there is a reduction in the formation of ammonia²⁴, hence less is excreted, as is shown in table 1. There is likewise a retention of phosphates and of chlorides^{11, 13}. In all probability there is withdrawal of chlorides from the stomach for this purpose, which would explain the absence of free hydrochloric acid in the stomachs of these patients when tested. The muscles themselves add lactic acid to the equation. In some instances, acetone has been recovered¹⁷ which is probably shielded by some of the alkali and excreted before normal oxidation can take place. Our findings are less constant in these respects than those of other authors^{2, 5, 11, 18}. All of these attempts to acidify the tissues are insufficient, and the tissue alkalosis persists with subsequent hyperirritability of the muscles which finally leads to tetany.

According to Brody,²⁵ hyperventilation will definitely increase the irritability of the cortex, possibly because of tissue alkalosis. Brody feels that there may be some other factor as well. However, hyperventilation affects the patients described above in greater degree than it ordinarily does those people who overbreathe voluntarily. It is felt that this difference is due to the synergistic effect, described by Brody, occurring when hyperventilation is instituted after previous cortical stimulation from other sources. In such a state as that of fear or of any of the emotional reactions, adrenalin is probably the cortical excitant, instead of strychnine which was used by Brody.

The stimulation of the cardiac center by adrenalin causes an increase in the rate-volume output of the heart, after preliminary slowing of the heart due to an initial rise in blood pressure. However, when hyperventilation is present the results are more complex and somewhat more variable. McDowell²⁶ found that, when carbon dioxide is washed out of the blood stream by hyperventilation, there are two effects: (1) vasodilation due to central vasomotor control stimulation, and (2) vasoconstriction due to direct action on the peripheral vascular bed. In some patients the first mechanism seems to be in control, in others the second seems to predominate, and in still others there seems to be a balance, so that a variety of changes in the blood pressure and sensations due to change in the peripheral vascular bed may be predicted because of the variety of responses in adjacent areas. The important principle to remember is that this variety of reactions has the same cause, and can be managed according to the same regimen of treatment. Roome²⁷ supports the contention made by McDowell, and states that the addition of 5 per cent carbon dioxide to the inspired air will control these changes in the

peripheral vascular bed According to McDowell, in animals this response is definitely attributable to a local chemical action and not to a nervous one, for there is no evidence of nervous stimulation such as dilation of the pupil or acceleration of the heart rate However, in human beings there is little doubt, from the emotional nature of the onset of the disturbance, that the action of adrenalin is also a factor, and that the hyperventilation is more or less involuntary—at first as a natural sequel to the emotion It is easy to see that local anoxemia may exist and be a factor in the cause of tetany No studies have been made on the content of oxygen in the capillary blood supply to these regions, so that there is no definite proof of this statement However, Striker, Goluben and Tarchanoff²⁸ have shown that alkalization of capillaries by local application will cause constriction of the vessels of the bed Severini and Krugh²⁸ stated that carbon dioxide will dilate the capillary bed In cases of spasm, the constriction remains until muscle metabolites form to reduce the pH at that point, and then the spasm relaxes

In connection with this syndrome, the presence of the symptoms of hyperthyroidism has been noted in patients seen in the authors' clinic These patients have been treated by psychotherapy, and have improved It is believed, however, that they suffer from this syndrome rather than from direct stimulation of the thyroid There is no chemical evidence of any effect on the parathyroids The stimulation of the gonads is a matter of conjecture No observations on this subject have been made, although it is evident that work should be done It is possible that in the sexual act, the orgasm is, in a sense, the result of hyperventilation tetany In the process there is increase in the respiratory rate, increase in the irritability of the muscles that control the act of erection, and finally there is tonic spasm of the muscles of the sexual organs and of the skeletal system as well How studies can be made under these conditions remains to be discovered, at any rate, the problem warrants consideration

It is suggested by the work of Pottenger¹⁶ that in addition to the suppression of free hydrochloric acid, dilation of the stomach and contraction of the sphincters would cause symptoms increasing the neurosis The same is true of the effect on the urinary bladder, gall-bladder and renal pelvis in these patients who are really suffering from a form of sympathetico-tonia There is spasm of the internal sphincter and trigone, and dilation of the bladder These symptoms, together with those resulting from direct cortical irritation, are sufficient to augment the neurosis, they cause the patient to feel ill, and thereby stimulate anxiety about his health—and the vicious cycle becomes complete Repeated cystoscopy, or other local treatment, tends to augment changes in the mucous membranes and leads to further structural change

It is well at this point to mention that another form of physiological disturbance has been observed in the psychogenic upset described above Two patients were seen who had been so stimulated that hyperhidrosis occurred

which was severe enough to cause a hypochloremia similar to that found by Piersol and Karr²⁹ in postoperative vomiting, in complications of peptic ulcer, and in hypertensive heart disease following the use of low salt diets. This portion of the subject is to be enlarged upon and reported at a later date.

The subject of seasickness, car-sickness (from riding in street cars, motor cars, and other rapidly moving conveyances), and air-sickness has attracted our attention over a period of several years. The close connection between the labyrinth, muscles of the eyes, and the gastrointestinal tract is well known. From personal observations upon many subjects in this group, it became apparent that anxiety is a significant factor in preparing the individual for the episodes which are so distressing to travellers. It is not assumed that certain subjects may not have over-sensitive labyrinths, or functional disturbances in the several structures participating in the production of these symptoms. However, the fact that most persons can become accustomed to the motions of conveyances, and the well known beneficial action of certain measures used in prevention and treatment (namely, sedatives such as bromides, antispasmodics such as atropine, peripheral dilators such as the nitrites, and inhalation of carbon dioxide) suggest that the anxiety state is more important than is generally appreciated. The termination of a bout of seasickness after several days may be promoted by the production of acidosis which compensates for the alkalosis induced by prolonged vomiting and anxiety combined.

Another problem—one which confronts those engaged in commercial conquest of the stratosphere—relates to altitude-sickness. Unless this problem is solved, the hazards of prolonged flight at altitudes above 12,000 feet will retard development. So far, attention has been centered chiefly in the reduced oxygen tension at high elevations. We proposed some time ago that a careful study be made of the concentration of carbon dioxide in the cabins of airplanes at these high altitudes. If ventilation is maintained and supplemented by oxygen and the carbon dioxide is lost, it would appear that subjects would suffer. Theoretically, if the respiratory mechanism is to function adequately, the carbon dioxide concentration should be kept at a higher level than normal. Experiments with this point in mind should be performed. The symptoms suffered by many of the subjects studied suggest a state of alkalosis.

The subject of hysteria is of historical and practical interest. It is our opinion that theoretically the episodes can in many instances be explained by the presence of the anxiety state, with extreme effects upon the psyche and periphery. The stocking-and-glove anesthesia is more likely a disturbance caused by limitation of the blood supply to the peripheral nerves, than due to central effects upon the peripheral nerves themselves. One cannot exclude blocks in the somatopsychic pathways wherein the registration of sensation from the periphery is wanting.

TREATMENT

Treatment of patients suffering from this condition should be divided into two types palliative and curative. The latter procedures consist of the use of psychotherapy by such means as psychocatharsis, reeducation, reassurance, and the substitution of a "non-fear" meaning in situations where desensitization is needed. The palliative measures or medicaments have very definite use for several reasons. Through immediate relief of symptoms, part of the cause of the neurosis is removed—namely, that portion dealing with the patient's concern regarding his health. He feels well for the first time in months, and therefore the emotional rapport with the physician is made stronger, so that the psychiatric procedures mentioned above may be performed much more easily. Also, the demonstration illustrates to the patient the mechanism of the physiological difficulties which he himself has caused, and the results are so dramatic that he is able to follow the procedure and to appreciate what the results mean to him. He is then in a position to check the physical changes at an earlier period, and to save himself from more profound disturbances.

The use of any agent that will break the course of events described in chart 1 will accomplish this purpose. The first group of measures are those which help to control the acid-base balance. These were used in the patients of our series. The inhalation of oxygen-carbon dioxide gas (70 per cent O to 30 per cent CO₂) is most effective³⁰ both in speed and adequacy. When the apparatus is not at hand, a paper sack inverted over the patient's head and sealed with adhesive tape, is successful. Some patients have responded to drinking small quantities of carbonated water or beer. Although these methods work well in convulsive attacks, it is found of advantage also to place these patients on an acid-ash diet, to reduce the fluid intake to 500 c c, and to administer ammonium chloride in dosage^{30, 31} as large as one gram, given by mouth in capsules from three to six times a day. A suitable prescription is as follows:

| | |
|--|-------|
| Ammonium chloride | 30 0 |
| Fld ext licorice | 20 0 |
| Syr yerba santa | 75 0 |
| Cinnamon water q s ad | 120 0 |
| Sig One teaspoonful 3 to 6 times per day | |

Or, simply the use of the *Mistura glycerhizae co* as the vehicle is successful. Chloride ions may not be as effective as carbon dioxide for Douglas and Havard³⁰ have shown that carbon dioxide permeates the respiratory center more quickly than chloride ions.

The next two methods are projected for future work. The first of these is based on the work of Levy and Ditz³² whose studies were limited to the phenoxyethylamine and orthomethoxyethylamine compounds. They tested the action of drugs in these groups on the heart action and respiratory rate in dogs, on the intestine *in situ* of the dog, and on the isolated intestine of

the guinea pig They followed the metabolism of the glucoside in the rabbit, and the toxicity by intravenous route in the mouse Of the group of eight drugs, there is one that will prevent vasoconstriction, inhibition of intestine, and increase in the respiratory rate—and that compound is *phenoxyethanolamine 2 ethane* This preparation has to be given prior to the expected extravasation of adrenalin, and is really preventive rather than curative So far as is known, this group of drugs has not been used in the treatment of human beings Other better known drugs have been used these are ergotamine, yohambin, hydrastin and quinine Their use is preventive also

Another method is suggested by Pottenger's reports¹⁶ After proving, by the tests he has outlined, that a patient is sympathicotonic, one might endeavor to develop parasympathetic tone in opposition to the former state Pilocarpine, histamine, and acetylcholine are suggested by this author as a means of attempting to convert these people to a more median type A difficulty arises here because some people have excess in both systems, and this method would aggravate symptoms of parasympathetic tone which do not form a part of the picture described above

SUMMARY

The authors believe that there is a physiological background for the perseverance of an anxiety state as part of a psychoneurosis, that this background is produced by the constant presence of purely emotional disturbances, and that the resultant physiological state aggravates the psychic component to such a degree that a vicious cycle is instituted, the symptoms of which are manifold These symptoms increase the severity of the emotional tension, and, if they are prolonged, permanent structural change with the production of organic disease results

The mechanism is at first a repetition of attacks, from the stimulation by an emotion such as fear upon the sympathetic nervous system, which in turn becomes increasingly labile The mechanism is perpetuated by the effects of the stimulus on the system of self-defense, which is dispatched by the endocrine group This reaction causes a state of hyperirritability to exist through the presence of tissue alkalosis, tissue hydremia, and tissue anoxemia, and results in a state of tetany which may be regional or generalized

The symptoms of tetany, and allied manifestations such as tachycardia, distended stomach and dilated urinary bladder, are enough to aggravate the neurosis because of the patient's fear of impending dissolution Multiplication of impulses increases the bombardment of the sympathetic nervous system, making repetition of the reaction more easy at subsequent intervals

The cure is accomplished through elimination of the fear-impulse by psychotherapy The symptoms may be alleviated medically, and by this means that part of the neurosis which is on the basis of anxiety concerning health may be eliminated Because of the subjective and objective improve-

ment in the patient's condition, contact for psychotherapy is more easily obtained. Medical treatment is directed toward preservation of the acid-base balance, toward decreasing the effect of adrenalin on the nerve-tissue by means of a known chemical antagonist, or toward converting the state of tone of the individual from extreme to moderate, whether parasympathetic or sympathetic in type.

RECTAL STENOSIS FROM ROENTGEN THERAPY REPORT OF TWO CASES^{*}

By T GRIER MILLER, M D , F A C P , *Philadelphia, Pennsylvania*

THE simultaneous occurrence under my immediate observation of rectal stenosis following roentgen therapy in two patients with carcinoma of the prostate has served to emphasize a significant hazard in the radiation treatment of various pelvic lesions. The complication apparently is well recognized by gynecologists, proctologists and radiologists, but internists generally have not fully appreciated its frequency or clinical importance. In one of the cases which I shall report a colostomy was required and in the other, it was under consideration when uremia, as a result of bilateral ureteral obstruction from secondary carcinomatous involvement, supervened and caused the patient's death. In each of them a diagnosis of rectal irritation from roentgen exposure was made early in the course of the therapy and in each, ultimately at autopsy, an intense fibrosis of the rectal wall with narrowing of the lumen was demonstrated.

An important report on the type of the rectal lesion produced by radiation and on its symptoms and diagnosis has recently been presented from this hospital by Ferguson¹. He has also reviewed the literature and given certain clinical and laboratory data on eight cases personally studied: six irradiated for carcinoma of the cervix, one, for carcinoma of the urinary bladder, and one, for carcinoma of the prostate. I wish somewhat more fully to trace the development of the lesion in my two cases and to emphasize its relation to undesirable radiation effects in other parts of the body.

CASE REPORTS

Case 1 † M J G, a physician of 72 years, who had first consulted me 17 years previously because of a transient attack of kidney colic, due to the passage of a small calculus, and subsequently from time to time for minor arthritic symptoms, complained in August 1934, of bladder irritation. He was able to void only 35 c c of urine at a time. I found his prostate enlarged and indurated. Three competent urologists ‡ considered that the left lobe contained a malignant lesion and that the case was inoperable. Roentgenological study of the bones was negative for metastases. Roentgen therapy was decided upon.

The first series of treatments § was begun on August 22, 1934 (see table 1 for details of total roentgen therapy). On October 30, one of the urologists (Pelouze)

* Received for publication August 16, 1937.

From the Gastro-Intestinal Section of the Medical Clinic, Hospital of the University of Pennsylvania.

† Included in Ferguson's series of 8 cases.

‡ Dr P S Pelouze, Dr S W Moorhead and Dr Alexander Randall.

§ The roentgen therapy in these cases was given by Dr E P Pendergrass and Dr G W Chamberlin of the Radiology Department of this Hospital.

TABLE I
Details of Roentgen Therapy in Cases 1 and 2 *
(Data submitted by Radiology Department)

* Irradiation factors 165 K V , constant potential, 15 ma , 50 cm distance, 2 mm Cu or Thoreus filter equivalent to 2 mm Cu All measurements are as in air

reported marked diminution in the size of the prostate but persistent induration, by that time the patient was passing as much as 110 c c of urine at a time Toward the end of the second series of treatments he developed, in addition to subcutaneous edema of the lower abdomen, some diarrhea and bladder irritation, recognized as due to the radiation, but the latter phenomena soon subsided and his urinary output at a single voiding amounted to 260 c c His urologist then reported that the gland was little above normal in size and that the mass, previously felt in the left lobe, had disappeared He stated, furthermore, that had he not seen the patient before he could not then have diagnosed the presence of a malignant lesion

Soon after the third series of treatments (given May to June, 1935) he began to pass mucus by bowel and to have much rectal irritation On October 8, a barium enema study showed marked narrowing of the lumen of the rectum, sigmoid and descending colon Cystoscopic investigation showed an elongated posterior urethra

with a definitely raised bladder neck and 175 c c of residual urine, the prostate itself still was not very large. A trans-urethral resection by Dr. Randall was done on October 18, after which he again became asymptomatic and was able to go back to his work. On December 10, his residual urine was only 10 c c.

Subsequent to the fourth and final series (given December 1935 to January 1936) he seemed in excellent general condition, and on March 14, Dr. Randall reported that his prostate showed only a little deep induration and some slight fixation. On June 20, he again reported on the prostate as follows: "flat, much softer than heretofore, rather finely nodular and not sensitive, residual urine 30 c c."

In August, however, he complained of marked rectal pain, tenderness and bleeding, with bouts of constipation and spasmodic pain on attempts at defecation, for which I referred him to a proctologist (L. K. Ferguson). He found marked edema and hypertrophy of the wall of the rectum and capillary bleeding from the mucosa on the slightest trauma, effects which he unhesitatingly attributed to the irradiation.

With astringent applications and a non-residue diet the rectal symptoms subsided, but during September another trans-urethral prostatic resection was necessary. Again he returned to his work and felt reasonably comfortable, but by December 1, he had developed additional edema and marked capillary dilatations of the lower abdominal wall and had some incontinence of urine alternating with retention which required catheterization. At the same time his stools were beginning to be of small caliber and ribbon-like, sometimes he had fecal incontinence. I found, on digital examination, an annular mass in the rectum with marked constriction of the lumen, which I at first thought was due to a malignant rectal lesion. By December 28, however, the rectal wall was less indurated and a finger could pass through it, as though the stenosis were due merely to edema of the wall.

In spite of this, on January 4, 1937, Dr. Randall reported improvement in his local condition with "softening of the prostate and surrounding tissues, no fixation or stony hardness, residual of 30 c c."

On March 10, he complained of a feeling of obstruction in the rectum and was unable to secure even a small liquid evacuation without a strong laxative. He was moderately anemic and emaciated in appearance, though his weight, because of the edema about the lower abdomen and back, was as usual. Again a rectal mass was palpable, but the proctoscope revealed only edema.

On April 3, he was admitted to the hospital because of marked abdominal pain and distention, fever and inability to evacuate the bowel. Rectal obstruction, due to edema and fibrosis of the bowel wall from radiation, was diagnosed. A catheter, however, could be passed slowly through the constricted area of the rectum, but only a small amount of fecal material could be washed out. Intubation of the small bowel from above allowed the escape of much gas and fluid with relief of the distention. A large mass was then felt in the right kidney area. A colostomy was considered, but he promptly became anuric, his urea nitrogen concentration rose to 140 mg per cent and he died April 7, 1937.

Autopsy revealed a primary carcinoma of the prostate with secondary involvement of the urinary bladder, chiefly about the trigone and the ureteral orifices, and bilateral pyonephrosis. The rectum itself was not involved in the malignant process, but, according to the pathologist (O. N. Smith) "in the rectum, beginning about 3 cm from the anal orifice and extending proximally for about 12 cm, there was a brawny thickening of the wall, most conspicuously involving the muscularis and simulating the hypertrophic changes seen in pyloric stenosis. This markedly constricted the caliber of the lumen, so that the index finger could be passed only with considerable force. Although the rectum was adherent to the posterior surface of the bladder, the diffuse involvement of its wall was not grossly neoplastic." Dr. Morton McCutcheon reported on his microscopic study of the sections as follows:

"There is marked chronic proctitis, characterized by mucosal destruction and by submucosal edema, fibrosis and inflammatory exudate. The inner muscularis is markedly degenerated, vacuolated with fat, and conspicuously replaced by fibrous tissue. Several arterioles are markedly hyalinized. The outer muscularis is less damaged. The fibrosis and muscular degeneration are much more marked in the rectum than in other sections of the sigmoid, small intestine and stomach."

COMMENT ON CASE 1

It will be noted that following the second series of treatments, and about four months after the beginning of radiation, diarrhea was first observed. Following the third series, five months later, he was passing much mucus by rectum and about one year after the first radiation a barium enema showed marked narrowing of the lumen of the rectum, sigmoid and descending colon. Again, however, he became asymptomatic, and in spite of the necessity for a prostatic resection (to relieve bladder retention) and a fourth series of roentgen treatments, he had no further significant rectal symptoms until August 1936, two years after the first treatment. Then he was proctoscoped for the first time and the examination disclosed rectal edema, hypertrophy of the wall and capillary bleeding. In spite of these local phenomena his rectal symptoms again subsided temporarily, but four months later he became constipated, had spasms of pain on defecation and the stools, when formed, were ribbon-like in character. Digital examination showed marked narrowing but the finger could be introduced slowly, apparently as the edema was reduced by pressure. This observation was subsequently confirmed by the proctoscope. Autopsy four months later, however, showed not only edema but true fibrosis of the wall.

Thus it seems clear that, although early he developed some irritation of the rectal wall, it was transient as also was some of the edema that occurred later, and not until after almost two and a half years did he develop the true fibrous and stenotic lesion which was found at autopsy.

Case 2 E. M., male, 72 years of age, a business man with large responsibilities, was referred to me by Dr. Isaac W. Kingsbury, of Hartford, Conn., on March 8, 1935, complaining of epigastric discomfort, relieved by alkalies, and of attacks of substernal distress with reference into the left arm after physical and mental strain. He was of the tall, thin, duodenal ulcer type, obviously arteriosclerotic, had systolic murmurs at the apex and base of his heart but no enlargement, and a blood pressure of 130 systolic, 85 diastolic. His prostate was moderately enlarged and firm. Urine, blood and stool examinations were negative. Free hydrochloric acid was present in excess in his gastric contents. An electrocardiogram showed some extrasystoles and evidence of myocardial damage. Gastrointestinal roentgenological study revealed a large active duodenal ulcer.

On May 17, 1935, Dr. Alexander Randall found characteristic evidence of prostatic malignancy. Roentgen study of the bones showed no metastases. Roentgen therapy was started at once (table 1). After the first series of treatments the prostate was much improved—smaller, more elastic and less nodular. Meanwhile he had developed some nausea and vomiting and had lost some weight (from 169 to 160 pounds). His ulcer symptoms had subsided and he had no more disturbing cardiac

attacks. Subsequently (July) some irritation of the skin in the hypogastrium developed and he had some frequency of bowel evacuations and irritability of the urinary bladder. On July 12, another gastrointestinal roentgen study showed the duodenal ulcer defect still present but associated with less spasm.

He had regained his usual weight by October and was in good general condition, but the left lobe of the prostate was larger and firmer. A second series of roentgen treatments was begun, and in the midst of that he developed marked edema and irritation of the lower abdominal wall, the buttocks and the perineal region. On completion of the series, however, the prostate seemed smaller and less hard. Again he had lost weight but, except for the skin lesions, one of which had ulcerated, was in good shape. Some fecal incontinence developed a few weeks later and the urinary bladder again became very irritable.

By January 27, 1936, he had regained his weight and the skin condition had improved though some hard edema persisted. He was able to go through the night without voiding.

On his return, in April, from a trip to the west coast, where he played as much as 12 holes of golf without incident, he had no special complaints, but his prostate was a little larger and seemed fixed to the bone on the left side. A month later he had some leg pains, suggestive of bone metastasis, but roentgenological examination was negative. On the basis of special vascular tests it finally was decided that the pains were on an arteriosclerotic basis and some "suction and pressure" therapy was given.

Prostatic examination by Dr. Randall, on September 24, revealed no new developments, but again he was having marked bladder irritation with nocturnal frequency. Shortly afterwards he developed a recurrence of the fecal incontinence. On November 25, he was complaining of stiffness in the loins and above the iliac crests but no abdominal masses could be felt. Edema of the groins and perineum was still marked. On December 18, he developed suddenly left chest pain and hemoptysis which suggested a pulmonary infarction, but roentgen study of the lungs showed only thickened trunk shadows, and he had subsequently no recurrence of the pain or hemoptysis. At the same time he developed some pain in the lower abdomen and back, but it was not persistent.

On April 17, 1937, he was complaining particularly of fecal incontinence, especially on urinating, alternating with constipation for 3 or 4 days. Blood frequently appeared in his stools. His appetite was impaired and he was losing weight (152 pounds). His sigmoid was full and doughy. On rectal examination marked edema of the wall with narrowing of the lumen as far as one could reach was found, and above that a mass in the lumen, probably fecal. Anteriorly through the edematous wall marked induration could be detected and a spreading prostatic lesion was suspected.

A week later he was again referred to the hospital because of abdominal pain, failure to evacuate the bowel and a suspicion of intestinal obstruction. The lower abdomen was tense and sore. Digital examination of the rectum showed diffuse induration but a smooth wall. A finger could barely be inserted. Finally a urethral catheter was slowly passed for 10 to 12 inches into the lower bowel and through that much blood and fecal material were evacuated, as a result of which he became quite comfortable. That procedure was repeated several times, but finally the results were unsatisfactory, and on April 30, a colostomy was performed by Dr. E. L. Elrson. The patient was quite alert after the operation for two hours, but then rather suddenly became distressed, cyanosed and dyspneic, developed a leaky skin and feeble pulse and died.

Autopsy by Dr. O. N. Smith showed that death had resulted from complete occlusion of the left coronary artery, already extensively sclerosed and calcified.

The prostate was only slightly enlarged and without induration suggestive grossly of carcinoma, but in the left lobe was a mass of gray tissue, 1 cm. in diameter, which microscopic study showed to be malignant. The rectum was markedly compressed by a mass of carcinomatous tissue which lay between it and the sacrum. The urinary bladder and ureters were not involved, but the lymph nodes along the abdominal aorta, about the head of the pancreas and those situated extraperitoneally in the pelvis were massively implicated. The sigmoid was adherent to the peritoneum below the pelvic brim and the upper rectum was more or less encased in carcinomatous tissue. The rectal mucosa, however, was not carcinomatous, but it was infiltrated with round cells and polymorphonuclears. The submucosa was edematous and fibrotic. The muscular cells were vacuolated and degenerated. The perimuscular adipose structure was infiltrated with fibrous tissue and edematous, and it contained an occasional metastatic carcinomatous mass, the result of lymphatic spread. The lungs showed metastatic lesions. The duodenum showed a small healed ulcer and the liver, multiple cysts, one of which contained 600 c.c. of fluid.

COMMENT ON CASE 2

The obstruction in this case obviously was due in part to the metastases which surrounded the rectum, but also in part to the edema and fibrosis of the rectal wall. The fact that a finger could be inserted into the lower rectum only very slowly, seemingly displacing fluid from the wall as it passed, and that a semi-rigid rubber tube could be introduced only in the same way left no doubt in the mind of the examiner that he was dealing with stenosis due to edema. The observations at autopsy, furthermore, indicated that the compression of the rectum by the metastatic lesions was not sufficient in itself to produce complete obstruction.

In this case also it will be noted that irritation of the rectum, indicated by diarrhea, occurred soon, about two months, after beginning radiation therapy, but was transient. Fecal incontinence came on after the second course of treatment, but that also subsided within a short time. It recurred, along with bladder irritation, however, after another year and then persisted until he developed definitely obstructive symptoms. Unfortunately no proctoscopic study was made in this case, but the frequent presence of blood in the stools suggests that, in addition to edema of the wall, telangiectatic areas, such as have frequently been demonstrated in other cases, were present.

GENERAL DISCUSSION

The intimate anatomical relationship of the rectum to the urinary bladder, the prostate and the cervix of the uterus accounts for its involvement when any of these organs is subjected to intensive radiation therapy. Although the portal of entry of the roentgen-rays through the skin may be altered from time to time, it is impossible to direct the rays so as to avoid almost maximal exposure of the deeper tissues in the immediate neighborhood of the lesion under treatment. The skin reaction, therefore, cannot be a measure of the effect produced internally on adjacent structures.

That intensive radiation is capable of producing irritating and eventually destructive effects elsewhere in the digestive tract is well ap-

preciated Desjardins² has reviewed the literature in reference to its action in the mouth, where in overdosage it produces ulcerative lesions, permanent telangiectases and serious dental disturbances, to its destructive action on the salivary glands, to the degeneration of epithelium, hyperemia, hemorrhage, atrophy and fibrosis which occur in the stomach, and to the mucoid degeneration, hyperemia, edema, ulceration and fibrous tissue replacement that take place in the small intestine Nelson and Hirsch,³ in reporting a case treated for suspected malignancy of a cervical lymph gland, state that the autopsy showed severe necrosis and scarring of the pharynx, larynx and upper parts of the trachea and esophagus Schenck⁴ has repeatedly observed irritation and edema of the larynx in patients given roentgen therapy for hyperthyroidism Elliott and Jenkinson⁵ had a patient who died as a result of intestinal perforation secondary to ulceration from roentgen therapy for abdominal Hodgkin's disease

Irritation of the urinary bladder, such as occurred in both of my cases, has been more often reported as a result of radium treatment for carcinoma of the cervix, but roentgen therapy also has been employed in most of these cases Everett⁶ refers to 18 cases, so treated, 7 of whom eventually developed a vesico-vaginal fistula and 11, bilateral ureteral stricture Dean⁷ has studied 47 women for lesions of the bladder incident to radiation therapy cystoscopic investigation, on an average of two and a half years after the therapy, showed ulceration and anemic areas surrounded by intense inflammation or punctate hemorrhage He stated that these lesions might follow comparatively light applications of irradiation

The incidence of rectal complications of radiation therapy is indicated by Bue and Malmgren's⁸ statement that in 2,073 cases subjected to pelvic irradiation for extra-rectal lesions they found 3.13 per cent that had rectal symptoms and a lesion discoverable by the proctoscope The onset averaged 11.6 months after treatment and the outstanding symptoms were bleeding, pain, diarrhea, urgency and tenesmus The proctoscope invariably showed telangiectases and bleeding Ulcers were present in 43 per cent of the cases

In a series of 520 cases of cervical carcinoma treated by irradiation eight months to eight years previously, Jones⁹ found seven instances of benign stricture of the intestine, although none of them had received excessive dosage according to present standards Only one had the stricture in the rectum, but five in the sigmoid The lesion in all instances was an annular fibrous thickening, localized and obstructing the bowel Newell and Crossen,¹⁰ in a series of 371 irradiation cases, had five with rectal stricture, but all were of slight degree and satisfactorily treated by dilatation

Jones,¹¹ Ferguson¹ and other authors have recognized early and late phases of the rectal reaction to radiation the one occurring within a few weeks or months after treatment, the other, months or years later Jones, whose observations were made on women with cervical carcinoma who received radium, stated that a dose sufficient to cure the lesion would produce erythema of the rectum and that the early symptoms of the latter were a

burning sensation and frequency of defecation, while later, after six to eight months, in the more severe cases, marked pain and tenesmus with blood and mucus might develop. Ferguson, whose experience has included patients treated not only with radium but also only with the roentgen-ray emphasizes the severity of the early symptoms chiefly in the radium cases. This seems reasonable since they receive a larger dosage of irradiation at one time. In neither of my cases was anything more than a slight and transient diarrhea, with the occasional passage of mucus, noted in the first phase of the reaction. In spite of this, both eventually, after an interval of freedom, developed the characteristic late symptoms: spasms of pain on attempt at defecation, diarrhea alternating with constipation, marked tenesmus and bleeding with and after each bowel movement. On two occasions in one of the cases a proctoscopic examination, made late in the course of the illness, revealed a contracted, edematous and bleeding rectal wall. The other case was not proctoscoped, but in both, the autopsy findings demonstrated clearly the presence of marked edema and fibrosis producing stenosis. Telangiectases were not observed, but since they have frequently been described in such cases it is to be assumed that they were present and accounted for the bleeding.

CONCLUSION

Two cases of stenosis of the rectum, due to intensive radiation therapy for carcinoma of the prostate, are presented in order to call attention to its occurrence. Although in each of these cases the malignant lesion had not been eradicated by the radiation and early death was inevitable, it is believed that the recognition of such rectal stenosis in certain other patients, in whom the primary lesion is under control, may lead to appropriate surgical therapy and be life saving.

PANCREATITIS AND DIABETES *

By HERMAN O MOSENTHAL, M D , F A C P , *New York, N Y*

THE involvement of the pancreas as a cause for diabetes is, to a great extent, taken for granted. The exact changes in the pancreas responsible for the development of diabetes are not clearly defined. The situation is a good deal as though all pulmonary conditions—tuberculosis, the pneumonias, abscess, bronchiectasis, asthma, passive congestion—were classified as a disease entity characterized by expectoration and all treated alike on that basis.

Certain phases of pancreatic pathology—carcinoma, cyst, adenoma—are well established, but the lesions resulting in diabetes are not satisfactorily evaluated. An attempt will be made in this paper to correlate the changes in the pancreas with the various manifestations characteristic of diabetes. The gradual development of knowledge in regard to the anatomical and the functional pathology of the pancreas warrants an effort of this sort at the present time, though the conclusions reached are tentative only and await further clinical and laboratory data for their elaboration.

PATHOLOGY OF THE PANCREAS IN DIABETES

An involvement of the majority of the islands of Langerhans causes diabetes, the pancreatitis resulting in such lesions may be chronic or acute, permanent or transient.

CHRONIC PANCREATITIS

Chronic pancreatitis develops in elderly persons because of arteriosclerosis and senescent processes. This form of chronic pancreatitis may be regarded as primary chronic pancreatitis. When the chronic pancreatitis is the sequel, through scarring, resulting from an acute pancreatitis or from pancreatic duct obstruction, it may be considered as secondary chronic pancreatitis.

PRIMARY CHRONIC PANCREATITIS

This type of pancreatitis results in the slowly progressive form of diabetes which occurs in late middle life and in old age, it is generally known as the essential diabetes of Naunyn, and should be ascribed to the degenerative changes incident to advancing years. It should be sharply distinguished

* Received for publication September 15, 1937.

Acknowledgment is made to Dr. S. H. Schechner for the reference of Case 4, to Dr. R. F. Carter for the operative findings, and to Dr. M. Bruger for many of the data on the same patient.

from the forms of diabetes characterized by exacerbations and found in younger individuals

Warren calls attention to the occurrence of three predominating lesions in the islands of Langerhans in his series of 259 diabetic pancreases, as follows

| Total Number of Cases—259 | |
|---------------------------|----|
| Normal | 69 |
| Fibrosis | 69 |
| Hyaline | 89 |
| Hydropic degeneration | 15 |

The above tabulation furnishes data only in regard to the qualitative changes in the islands of Langerhans and gives no information about a diminution in their number. It may very well be that in the group designated as normal, a number of islands have disappeared and left no trace which can be identified under the microscope.

Hyalinization of the islands of Langerhans occurs almost entirely in persons over 40 years of age, it is also found in non-diabetics. Fibrosis, like hyalinization, is more frequent in older individuals and yet, though common, is not often mentioned as a cause for diabetes. Joslin subscribes to the idea that fibrosis of the islands is nearly as common a finding as hyalinization. Fibrosis and hyalinization of the islands may appear in the same pancreas and the two lesions may even be combined in the same island. It is tempting to assume that both fibrosis and hyalinization of the islands are part of the aging process and the arteriosclerosis incident to human existence.

SECONDARY CHRONIC PANCREATITIS

Secondary chronic pancreatitis results from destruction of the pancreas brought about by obstruction of the pancreatic ducts, through pancreatic calculi or external pressure, by acute pancreatitis, and by pancreatic cysts or hemorrhage within the pancreatic tissue. The subsequent development of diabetes depends upon the number of islands of Langerhans which are destroyed. Very frequently, probably in most cases, too few islands are involved to result in diabetes. Especially noteworthy in this connection is the experimental observation of MacCallum that after ligation of a pancreatic duct, all the corresponding pancreatic tissue atrophies, except the islands of Langerhans, which are preserved, this has been verified in human beings with long standing obstruction of the pancreatic ducts.

The diabetes resulting from secondary chronic pancreatitis is usually mild and non-progressive (see Case 5) unless there is a recurrence of the process which extends the involvement of the islands of Langerhans.

ACUTE PANCREATITIS

Fitz in 1889 designated the varieties of acute pancreatitis as hemorrhagic, gangrenous and suppurative, while these three types of injury are

still recognized they have come to be regarded as parts of the same process, that is acute pancreatitis (Pratt, Warfield, MacCallum and others) Pratt says "The subdivisions made by Fitz into hemorrhagic, gangrenous and suppurative forms of acute pancreatitis represent different stages in the same pathological process which begins with necrosis of the pancreas" This severe form of acute pancreatitis, characterized clinically by marked epigastric pain, shock and collapse, was the only one recognized for a long time and is the only one considered by many clinicians today

Pratt was one of the first to describe the mild cases, differing largely from the severe cases in that a smaller amount of pancreatic tissue was involved Since then, Warfield, Dragstedt, Haymond and Ellis, and Rich and Duff, have made the same observation Such minor involvements of the pancreas according to all these observers are frequently found The turbulent course of diabetes in the young is probably due to recurring attacks of this sort The rarity of acute pancreatitis, as stressed by Root, would consequently apply only to the severe form and not to the milder, non-fatal attacks

The etiology of acute pancreatitis has been a matter of considerable debate The majority of authors specify diseases of the gall-bladder as being primarily responsible Dragstedt, Haymond and Ellis, in an intensive study of this problem, come to some very important conclusions Edema and hemorrhage of the pancreatic parenchyma are frequent findings, they constitute milder attacks of pancreatitis, which may develop into necrosis, limited or extensive, that is, the significant change of severe acute pancreatitis These authors believe that bile, and infection by *B welchii* are the separate determining factors in bringing about the necrotic process (This is in contrast to the opinion of others, e g, Rich and Duff quoted subsequently)

According to Dragstedt, Haymond and Ellis, it is probable that approximately 60 per cent of the cases of acute pancreatitis in man have developed as a direct result of the passage of bile into the pancreatic ducts, the causes of the pancreatitis in the remaining 40 per cent are (1) extension of infection via the lymphatics from an infected gall-bladder or neighboring viscus, (2) trauma, (3) hematogenous infection, as in mumps, (4) stasis of the pancreatic juice—plus infection, (5) reflux of the duodenal contents into the pancreas

Rich and Duff, from their experimental and pathological studies, develop the idea that the main cause for acute pancreatitis is occlusion of the pancreatic ducts, the stoppage may be brought about by gall stones lodged in the papilla of Vater, or as they stress, by metaplasia of the epithelium of the branches of the pancreatic duct The latter condition was found to exist in 18.6 per cent of autopsies in individuals over 25 years of age They believe, in contrast to Dragstedt and his co-workers, that because of the obstruction trypsin and steapsin are liberated and result in necrosis of the

arteries, producing hemorrhage, necrosis of other elements in the pancreatic tissue, and in fat necroses

The clinical manifestations resulting from chronic or acute pancreatitis are of three varieties, each caused by the involvement of a specific element in the pancreatic tissue. One or the other of these impairments may be present singly or they may co-exist. These symptom complexes will be discussed under the heads

- 1 Carbohydrate metabolism
- 2 Fat metabolism
- 3 Blockage of the pancreatic ducts

CARBOHYDRATE METABOLISM AND THE PANCREAS

Chronic pancreatitis, due to arteriosclerotic and senescent lesions in the islands of Langerhans, is accepted as being the cause of the mild, slowly progressive diabetes of older persons. This form of diabetes was called essential diabetes by Naunyn and is still known by that name.

In younger individuals, diabetes pursues a much more irregular course, punctuated by periods of marked loss in carbohydrate tolerance. Wilder (quoted by Warfield), and Warfield have suggested that repeated attacks of mild acute pancreatitis, followed by some permanent injury to the islands of Langerhans, might be the reason for this type of diabetes. Case 1 (table 1) is an example of this sort.

CASE REPORT

Case 1 S R, student, male, in September 1933, at age 18, developed a glycosuria, he had been 14 lbs overweight, complete physical examination, except for glycosuria and hyperglycemia, was negative in all respects.

The details of the course of the diabetes are shown in table 1.

In any case of acute pancreatitis the degree to which the carbohydrate metabolism is implicated will depend upon the number of the islands of Langerhans that are involved so that an acute pancreatitis may or may not be accompanied by hyperglycemia and glycosuria, an acute pancreatitis may result in diabetes (Case 6), it may bring about no change in the severity of an existing diabetes (Case 5), it may aggravate a diabetes permanently (Case 1), or it may cause the transient appearance of diabetes which subsequently clears up (Case 4).

The oxidation of fat is in part associated with the carbohydrate metabolism. It is an old and accepted principle in the metabolism of diabetes, formulated by Magnus Levy, that "The fats burn in the fire of the carbohydrates." This does not mean that the oxidation of fats depends entirely on the utilization of glucose but only that the oxidation of B-oxybutyric acid is contingent upon the carbohydrate metabolism. The change from the fatty acids of a chain of 16 or 18 carbon atoms, that go to make up

Table 1 Case 1 Four year history of the changes in the loss of sugar tolerance in a diabetic aged 18 years, at the onset of the diabetes While there have been no signs or symptoms of pancreatitis other than glycosuria, it is suggested that comparatively mild, recurring attacks of pancreatitis are responsible for the irregular progress of the disease

* Plain figures show regular insulin, italicized figures protamine, or protamine zinc insulin, the individual doses of insulin are separated by a dash

neutral fats, to the 4 carbon chain of B-oxybutyric acid is governed by other agencies An excess of B-oxybutyric acid results in diabetic acidosis and coma A markedly impaired carbohydrate metabolism, therefore, will be associated with acidosis and coma, but the oxidation of fats to the stage of B-oxybutyric acid does not depend upon the islands of Langerhans and their influence upon glucose oxidation Another part of the pancreas controls the transport and utilization of fat up to the point of B-oxybutyric acid formation The significance and symptomatology of this pancreatic function will be discussed in the next section on fat metabolism

FAT METABOLISM AND THE PANCREAS

Previous mention has been made of the fact that the complete oxidation of fatty acids and the prevention of acidosis depends upon the proper utilization of glucose. A closer study of cases of diabetes reveals the fact that the disposition of fat is a pancreatic function entirely apart from that of carbohydrate utilization or that of absorption of fats from the intestinal tract. The signs and symptoms of deficient fat metabolism noted in diabetes are

Hypercholesterinemia
Lipemia
Xanthoma
Fatty liver and spleen

Hypercholesterinemia occurs in some mild diabetics whose carbohydrate metabolism is well controlled and in whom there is no acidosis. The cholesterol content of the blood parallels the total fatty acids fairly well and may be taken as an index of the degree of lipemia.

Case 2 Male, aged 38, diabetes for four years, observed for more than one year. During that period no insulin was required, nine determinations of blood sugar taken after breakfast were normal, varying from 98 to 167, the blood specimens were always lipemic and the plasma cholesterol was distinctly elevated, ranging from 248 to 400. At no time was there acetone or diacetic acid in the urine. The physical examination was normal except for a large spleen which was tender and whose lower pole extended three fingers' breadth below the costal margin, the liver edge was at the costal margin.

This case was interpreted as being one of diabetes with very marked dissociation of the effects upon the carbohydrate and the fat metabolism. The distinct disturbance of the fat metabolism was evident from the persistent lipemia, the high plasma cholesterol and presumably fat deposits in the spleen, while the carbohydrate metabolism was scarcely affected, since there was only transient glycosuria, the blood sugar was nearly always at a normal level, insulin was not required and dietary restriction alone served to control the situation. The relationship between the elevated blood cholesterol and the control of blood and urine sugar in this instance, is not at all like that which is usually accepted, in that the successful management of the carbohydrate metabolism did not serve to reduce the high level of the blood cholesterol.

Another similar example of dissociated fat and carbohydrate metabolism is Case 3.

Case 3 Male, aged 57, diabetes discovered three years ago on routine urine examination, five years ago accepted on life insurance examination for a large sum. Forty pounds overweight for height and age, otherwise physical examination shows nothing of note. The interesting point in this patient lies in the fact that the plasma cholesterol was continuously high and had a tendency to rise in the face of fairly good control of the diabetes. From August 1935 to August 1937, plasma cholesterol determinations made at intervals, were as follows: 238, 200, 238, 261, 296, 312, 343, 312, 369, 278.

Lough and Killian report the case of a young male diabetic, aged 20, who after seven months' dietary indiscretion, developed xanthoma diabeticorum, lipemia and acidosis. The total fatty acids in the blood were 9,200 (normal 600) and the plasma cholesterol 1,072 (normal 180). In this patient, as in most similar instances, the xanthoma, the lipemia, the glycosuria and the acidosis all cleared up on treatment of the disturbed carbohydrate metabolism, however, here as in many other cases, there was a lag of the return to normal of the lipemia as compared to the blood sugar and the acidosis. This bears out the conception that both the carbohydrate and fat metabolism are affected by an involvement of the pancreas, yet they are not acted upon synchronously and, consequently, it is fair to assume that such changes are brought about by the suppression of a different pancreatic function.

The symptom complex of severe acute pancreatitis,—glycosuria, acidosis, rise of blood cholesterol, lipemia, xanthoma, fatty liver and spleen—often develops so precipitously as to produce a completely baffling picture that defies analysis, on the other hand, there are cases of pancreatitis recorded in which each of these symptoms appears individually and apparently independently of the others. Instances of acidosis without lipemia are common (Herbert), cases of pancreatitis with lipemia or xanthoma developing in advance of, or in the complete absence of glycosuria, are reported. These facts have led Wijnhausen (1921), Joel (1924), Brunner (1935), and Root (1936) to stress the idea that there is a specialized function of the pancreas, which checks lipemia, xanthoma, fatty liver and spleen, apart from the regulation of the carbohydrate metabolism effected by the islands of Langerhans.

A recent case of recurring pancreatitis, with an almost record level blood cholesterol and lipemia, is the following:

Case 4 Male, aged 35, first seen on April 24, 1936

History Acute appendicitis, not operated on, 1921 (in view of subsequent events this may have been an attack of acute pancreatitis). March 1935, passed a life insurance examination, September 1935, glycosuria discovered for the first time, December 1935, acute pain in the epigastrium which disappeared in a few days, April 24, 1936, a recurrence of the acute pain in the epigastrium which became so severe that operation was resorted to.

Physical Examination Markedly obese (85 lbs overweight for height and age), xanthomata were scattered over the neck, abdomen and legs. The edge of the liver was four fingers' breadth below the costal margin and the liver was distinctly tender, the spleen was not enlarged. The heart rate was 120, there was no other sign of collapse or shock, the patient walking about without embarrassment, and the blood pressure was 132 systolic and 94 diastolic. Otherwise a complete physical examination showed nothing of note.

Laboratory Observations April 24, twenty-four hours prior to the admission of the patient to the hospital, the urine sugar was 3.3 per cent and acetonuria was graded two plus. The plasma was markedly lipemic. The blood sugar was 400 mg per cent, the total plasma cholesterol 2037 mg per cent, and the total fatty acids in the plasma 1738 mg per cent. Leukocytes numbered 16,800 with 76 per cent polymorphonuclear neutrophils. April 25, on admission to the New York Post-Graduate

Hospital, the urine still showed marked glycosuria and acetonuria. The blood sugar had decreased to 214 mg per cent. The leukocytes now were 25,450 with 80 per cent polymorphonuclear neutrophils. The administration of 140 units of insulin in divided doses over a period of nine hours rendered the urine sugar and acetone free. Within 48 hours after the initiation of intensive treatment and immediately prior to the operative interference, the blood sugar had decreased to 180 mg per cent, total cholesterol to 1041 mg per cent, and the fatty acids to 394 mg per cent.

Table 2 - Case 4 The findings on the second and third days post-operative in a case of acute pancreatitis, showing the effect of single large doses of protamine insulin on the urine sugar, blood sugar and plasma cholesterol. The pre-operative cholesterol figures were much higher 2037 and 1041 mg per cent.

Operative Findings On April 27, Dr R. Franklin Carter operated at the New York Post-Graduate Hospital and his operative notes were: On opening the abdomen the gall-bladder was found to be distended but not acutely inflamed. The abdomen was filled with a yellowish-green pus. When the incision was extended the appendix was found to be hanging over the brim of the pelvis and adherent at the base but not acutely inflamed. The upper abdomen was searched. Adhesions were found between the hepatic flexure and the colon and the lateral abdominal wall. The adhesions were found to be fibrotic and in the adhesions there was found to be a yellow slough behind the colon involving the fat of the colon wall. The duodenum was normal. Looking up above the duodenum along the common duct, pus was found to be exuding through

an opening in the retroperitoneal covering of the common duct and draining into the abdominal cavity. Bile in the gall-bladder was found to be very thick, tar-like in character. *Operation* cholecystostomy—drainage of the abdomen. *Diagnosis* acute destructive pancreatitis involving chiefly head of the pancreas with biliary obstruction (No fat necrosis in abdomen). General peritonitis.

Post-Operative Course complete recovery, discharged 27 days post-operative.

Fifty to 75 units of regular insulin daily in divided doses did not control the post-operative glycosuria. Protamine insulin in single doses of 100 units, buffered by moderate amounts of orange juice every few hours, proved to be more satisfactory (table 2).

The lag of the plasma cholesterol as compared to the immediate response of the blood sugar and the glycosuria, as in the case of Lough and Killian and others, is very evident (table 2). This observation is borne out by experiments on human subjects in which a single dose of insulin did not produce any significant change in the blood cholesterol even though the blood sugar changed from a distinct hyperglycemia to hypoglycemia (Bruger and Mosenthal). The distinction between fat and carbohydrate control by the pancreas is thus stressed.

The subsequent history of this case showed that there was complete recovery from the damage to the pancreas, insulin was never required, an anti-obesity diet was followed for two months with a loss of 35 lbs, but at the end of that period he again "ate everything" including starches, and after eleven months had regained all the lost weight. The interesting points here are that the carbohydrate metabolism remained normal though there was some evidence of disturbance in the fat metabolism, the urine remained sugar free, the blood sugar, taken after breakfast, was 93 mg and 111 mg per 100 c c, and no insulin has been used, the plasma cholesterol values on the other hand were somewhat elevated being 256 and 343 mg per 100 c c. Uncomplicated obesity, as shown by Bruger and Poindexter, is characterized by a normal level of plasma cholesterol, the high figures here would consequently point to an involvement of the fat regulating structures of the pancreas, whereas the islands of Langerhans controlling sugar utilization had made a complete functional recovery. The independence of the influences of the pancreas upon the fats and the carbohydrates is again emphasized.

The tenderness of the liver in this case and the tenderness of the spleen in Case 2 are noteworthy. It may be that deposition of large quantities of fat in the liver and spleen may result in tenderness and this may prove to be a sign of diagnostic value.

The solution of the problem of the existence of a disturbance in fat metabolism through the pancreas, apart from that regulating the carbohydrate metabolism, may be provided by the discovery of the hormone "lipocain" by Dragstedt, Van Prohaska and Harms. In their own words this material is described as follows: "a specific substance has been obtained in alcoholic extracts of beef pancreas, that on oral administration to depancreatized dogs treated with insulin, permits survival and prevents and relieves the fatty degeneration and infiltration of the liver of these animals. This substance, for which the name 'lipocain' is suggested, is believed to be a new

hormone that is concerned in some way with the normal transport and utilization of fat "

The "lipocaic" awaits clinical trial. It is sincerely hoped that it will prove successful in controlling the hypemia and hypercholesterinemia, so common in diabetes, and the more severe, though less frequent, disturbances—the fatty liver and spleen, and xanthomata. If the thesis proposed here and by others, that there is an independent control of fat and carbohydrate metabolism by the pancreas, is correct, then it would be expected that "lipocaic" should set aside the derangement of the fat metabolism in diabetes, and it might be particularly valuable in preventing the dreaded vascular complications of the disease.

BLOCKAGE OF THE PANCREATIC DUCTS

The pathognomonic sign of occlusion of the pancreatic ducts is the occurrence of "pancreatic stools", the typical pancreatic stools are soft, very voluminous in shape, size and consistency, when passed into a bed pan they resemble those of cattle, they are yellowish and glistening (due to the presence of free fat), they are malodorous (due to putrefaction, since the proteins are hemmed in by free fat which permits the growth of anaerobic organisms, but prevents the digestion and absorption of meat, etc.), there are usually from three to six of such bulky movements a day, the laboratory tests of these excreta are not as reliable as the macroscopic appearance just mentioned, free fat and undigested meat fibers should be seen on microscopic examination. There should be an absence of pancreatic ferment, the lack of which can be more reliably demonstrated by examination of the duodenal contents.

The signs of diabetes may precede the appearance of the pancreatic stools (Case 5), or may appear after the closure of the pancreatic ducts has become manifest (Case 6). There are many instances in which occlusion of the pancreatic ducts is not accompanied by diabetes as might be expected according to MacCallum's findings, previously mentioned, that uncomplicated blockage of the pancreatic ducts results in atrophy and sclerosis of the acinar tissue, while the islands of Langerhans are preserved. Whether an existing diabetes remains unchanged or undergoes an exacerbation with stoppage of the pancreatic intestinal secretion depends upon the presence or absence of pancreatitis and the involvement of the pancreatic ducts in diabetics. (Case 6 is abstracted from a previous publication, Mosenthal, 1912.)

Case 5 Male, first seen 12 years ago (1925) when he was 55 years old. There was then a mild diabetes which was readily controlled by diet. Progress was uneventful until October 1928 when there was some vague discomfort in the epigastrium. Two series of roentgen-ray films revealed no definite lesion. During April and May 1929, there was a series of chills and fever about once a week, the chills were severe and were followed by rises in temperature up to 104 and even 105 degrees. At this time typical "pancreatic stools" appeared. During the eight following years the

number and size of the stools could be checked only by the feeding of raw pancreas. The diabetes was not aggravated by the fever and has remained unchanged during the eight ensuing years.

*Case 6** Male, aged 20. During the latter part of November 1909, he had an attack of intense abdominal pain without diarrhea or fever, one month later a marked glycosuria was found, in January 1910 he had frequent attacks of vomiting accompanied by a "burning sensation" but no frank abdominal pain. In February the vomiting ceased, the stools however at this time changed in character, became large and putty-like and were said to resemble "mavonnaise" the stools have continued unchanged up to the present (May 1910). The results of pancreatic medication are given in table 3.

TABLE III
Urine in Twenty-Four Hours

Table 3 Quantitative urinary determinations, and medication in Case 6, pancreatic steatorrhea.

Note. Lack of effect of pancreatic extract, and the good result (reduction of number of stools) with raw pancreas, the raw pancreas brought about a better absorption of fats as shown by the rise of ammonia and acid substances in the urine.

The relief from pancreatic stools can be accomplished only by the administration of raw pancreas. The use of any of the commercial extracts has proved to be valueless (see the effect of "Pankreon," table 3). Case 5 has been taking raw pancreas with satisfactory control of his bowels for eight years, every time he omits the pancreas, the steatorrhea returns. Bargen, Bollman and Kepler recently reported the successful control of pancreatic stools by an extract of pancreatic juice administered in capsules, this should prove to be a great boon because raw pancreas has an exceedingly disagreeable, and to many persons, a very revolting taste.

It is interesting to note that the administration of raw pancreas in Case 6 (table 3) improved the absorption of fat a great deal as evidenced by the increase in the acidosis, today with the availability of insulin this ceases to become a clinical threat, but it is worth bearing in mind that uncontrolled steatorrhea may be a factor in producing malnutrition through non-absorp-

* Case 6 is abstracted from a previous publication (Mosenthal, 1912).

tion of fat, table 3 shows that the absorption of glucose or protein was little, if at all, affected by the administration of raw pancreas

SUMMARY

Clinical and pathological studies of diabetes point to the pancreas as the crucial organ responsible for the disturbed carbohydrate metabolism that constitutes diabetes. Chronic pancreatitis resulting from senescent processes is responsible for the very slowly progressive essential diabetes of Naunyn. Acute pancreatitis in its milder form, which is much more common than is generally supposed, probably is the cause for the stormy course, with many acute exacerbations, found in younger diabetics, pancreatitis will result in three sets of symptoms which may develop independently or be combined with one another, these are (1) interference with the carbohydrate metabolism bringing about hyperglycemia, glycosuria, acidosis and coma, (2) disturbance of the fat metabolism manifesting itself in a rise of the blood cholesterol, lipemia, xanthoma, fatty liver and fatty spleen, (3) occlusion of the pancreatic ducts and consequent lack of external secretion of the pancreas into the intestine, causing the characteristic stools and preventing the absorption of fat

THE VARIABILITY OF BASAL METABOLISM. SOME OBSERVATIONS CONCERNING ITS APPLI- CATION IN CONDITIONS OF HEALTH AND DISEASE¹

By WALTER M. BOOTHBY, M.D., F.A.C.P., JOSEPH BERKSON, M.D., and
WILLIAM A. PLUMMER, M.D., F.A.C.P., Rochester, Minnesota

MEANS, discussing the value of the basal metabolic rate, says "It should be remembered that basal metabolic rates are never too low (except when a technical error or an inward leak in the apparatus occurs or when the subject goes to sleep) All the factors which tend to make a reading inaccurate tend to make it too high food, failure to eat properly, emotion, fever and so forth Therefore a single low reading has more significance than a single high one" Similar statements can be found in the writings of nearly all students of metabolism, including Benedict, DuBois, Krogh, Boothby and others

That an important truth of immediate practical interest for the standardization and clinical interpretation of determinations of metabolism is conveyed in such statements is not to be denied, and that adventitious departures from the usual "basal" conditions more frequently raise than lower the measured metabolism is true The term "basal metabolism" for that metabolism measured under defined conditions for standard and clinical purposes usefully emphasized this fact, especially in the early phases of the development of the subject But as Krogh has stated, it might have been better to have used the term "standard metabolism," for the entire concept has been confused by the implications of the term "basal" and the ideas it embodies From the truth that basal metabolism is generally lower than metabolism measured under "non-basal" conditions has grown the fallacious idea that basal metabolism is the *lowest* metabolism From the truth that basal metabolism is less variable than metabolism measured under uncontrolled conditions has insidiously grown an attitude toward basal metabolism as a quantity that is *fixed* These erroneous ideas are never given explicit statement, but they are tacit implications in a considerable amount of work, even important work by the best authorities

We wish in this essay to emphasize that "basal metabolism," as an actual observation is one made under certain defined standard conditions, conditions which while well considered and soundly established, are nevertheless to a considerable degree arbitrary, even if these conditions are rigidly adhered to, the measurement will be *variable*, even as is any biologic observation It

* Submitted for publication August 28, 1937

follows at once that there is no one *lowest* metabolism that has a prerogative to be considered *the* basal metabolism over any other measurement of metabolism made under standard conditions. Were this always realized explicitly, to mention only one consequence there would not be in serious investigations a casual identification of measurements of basal metabolism which are "the lowest observation," "the mean," "the first observation," and so forth for if basal metabolism is a variable, these are not equivalent. It is not to the point at the moment to question whether the distinction between these various representations of basal metabolism is of importance, the fact is that for purposes of certain investigations they are negligible and for others they are essential, but they cannot be *assumed* to be the same.

Once the aspect of variability of metabolism is clearly grasped and deliberately accepted, problems will present themselves, the solution of which will be immediately enlightening, and other old problems will be seen in a different view. It is for these reasons that we have embarked on a careful analysis of a large body of our data, both normal and pathologic, with due regard for the variable characteristics of the material as well as for its central character. Some of these results can be given here.

For the statistical analysis of variability we will make use of the Gaussian curve, the "curve of chance," and the measure of variability appropriate to it as expressed in the "standard deviation." While the correct technical use of statistical methods requires an intensive knowledge of the subject, only a few simple facts need to be known for an investigator unacquainted with the complexities of the subject to understand the significance of those results of our studies which we wish to present here. Therefore, before proceeding to the presentation of some of our findings, we shall review briefly some statistical essentials which will guide what follows.

The Gaussian or "normal" curve is a symmetrical curve, "cocked hat" in shape, and is completely defined mathematically for any given group by two constants, namely, the "mean" and the "standard deviation." The *mean* locates the center of the curve and is the usual *average*. It is calculated as usual by adding all the observations and by dividing the sum by the number of observations. The *standard deviation* (σ , sigma) measures the "spread" or variability of the curve, and it is the value obtained by squaring the difference of each observation from the mean, adding these squares, dividing the sum by the number of observations less one, and finally taking the square root of the result. In other words, $\sigma = \sqrt{\frac{\Sigma \Delta^2}{N-1}}$, where σ is the usual expression for the standard deviation, $\Sigma \Delta^2$ is the sum of the squares of the differences of the individual observations from their mean and N is the number of observations.

The application of the Gaussian curve of chance to problems dealing with biologic data such as we are concerned with arises from the fact that this curve has been found to describe the distribution of biologic observa-

tions, as well as the fluctuations of chance, in a wide variety of situations. It is therefore often referred to as the "normal" curve of distribution. Not all biologic data, of course, can be represented by the Gaussian curve, but if they cannot, that fact is also of significance. If the distribution of the data which are being studied follows the Gaussian curve, then the standard deviation will not only accurately measure the variability of those data in an easily expressed value, but it can also be used directly to give the proportion of cases falling within or outside of any stated limits.

The simplicity of the use of this function is shown in figure 1, where the upper curve represents in the unshaded portion the area within $\pm 0.6745\sigma$ or 1 probable error of the mean, and contains 50 per cent of the observations, and each shaded area in the outer horns of the curve represents 25 per cent of the observations. The middle curve represents in the unshaded portion the area within $\pm 1\sigma$ of the mean, and contains 69.3 per cent of the observations (it can be remembered as roughly $\frac{2}{3}$ of the observations), and each shaded portion outside represents approximately 15 per cent of the observations. The lower curve is the most important because, here, the unshaded center represents the area within $\pm 2\sigma$ of the mean, which is the commonly accepted critical limit. It contains slightly more than 95 per cent of the observations, and each outer horn contains only approximately 2.5 per cent of the observations. It is for the reason that the area within $\pm 2\sigma$ of the mean contains almost all (95 per cent) of the observations that 2σ is usually the limit of "significance." That is, if a value is found to be more than 2σ away from the center of a defined group, it is considered as probably not belonging to that group ("significantly different"), and this probability increases rapidly as the limit of 2σ is exceeded, as can be seen from the shape of the curve.

Bearing this in mind, one can see why the standard deviation should be calculated and the observations compared to the normal curve where possible. Instead of being indefinite about the number of cases that lie beyond any given distance from the mean, we can always refer to the value of $\pm 2\sigma$ and this will represent 95 per cent of the total.

A study of the variability of basal metabolism in normal subjects has just been completed by two of us (Berkson and Boothby), and some of the results may be summarized here. First, the variability of repeated determinations for the same person is to be considered, the intraindividual variability. For successive determinations within the same day the average sigma is 1 calorie per square meter per hour (3.0 per cent of the mean), for successive observations made on successive days, under the usual basal postabsorptive conditions, the average sigma for men and women is 1.5 calories per square meter per hour (4.1 per cent of the mean), and the distribution is Gaussian. The intraindividual variability is somewhat greater for women (1.61 cal per sq meter per hour, 4.7 per cent) than men (1.33 cal per sq meter per hr, 3.5 per cent), and this is attributable prob-

ably to the disturbing effect of the menstrual cycle on the metabolism It is not to be understood that the intraindividual variability is the same for all ages or for different persons of the same age In reviewing the published

FIG 1 Normal or Gaussian curve

data for the study referred to, we found that Prof F G Benedict had the record for maintaining constancy of metabolism over a long period, the value of his standard deviation being 0.7 calories per square meter per hour (2.2 per cent of the mean)

The variability as between different individuals of the same age, sex, weight, and stature—the interindividual variability—is greater than the intraindividual variability, for it consists of the variation that obtains for the single individual plus that which represents the differences between one individual and another. The sum of these is what we measure in calculating the variability of numerous observations of basal metabolism, each for a different individual (but all of the same sex, age, stature and weight). We found as the interindividual standard deviation for males under 20 years of age, 3.14 calories per square meter per hour (6.5 per cent of mean), and for those 20 years and over, 2.58 (6.7 per cent of mean). For females the standard deviation in the group under 20 years of age was 2.98 calories per square meter per hour (6.8 per cent of mean), and for those 20 years and over, 2.42 (6.9 per cent of mean). These estimates of interindividual variability calculated from single observations made on different individuals is composed, as we have said, of two parts, and we therefore refer to it as the *total* interindividual variability. One part is the variability inherent in repeated determinations for the same person, the intraindividual variability. The other part represents the variability from one person to another, the variability of the “characteristic” or the mean metabolism of different persons.

How much individuals differ from one another apart from their own inherent variability is of considerable biologic interest. However, it is manifestly impracticable to collect a large number of individuals of the same sex, age, stature and weight, and to make for each one a large number of observations to obtain the mean metabolism in order then to calculate directly the variability of those means. Fortunately the value can be estimated indirectly from the calculations already made. Since the total interindividual variability is the sum of the intraindividual variabilities and the variability of means which we are seeking, the variability of mean metabolism can be obtained by subtracting the intraindividual variability from the total. The subtraction is not to be performed by using the standard deviations themselves but rather their squares, because two independent variabilities add their effects as the square-root of the sum of the squares. The square-root of the difference of the squares of the total interindividual variability and the intraindividual variability then, gives the interindividual variability of means. Thus calculated we found for men the value 2.2 calories per square meter per hour (5.8 per cent of the mean), for women 1.81 calories per square meter per hour (5.2 per cent of the mean). Here we found in calories per square meter the variability of men greater than for women, whereas when we considered merely the variability of numerous individual observations we found the female variability larger. We have here, then, the conclusion that if the characteristic (mean) metabolism of the individuals of the species is considered, adult males are more variable than females. Repeated determinations for individual females are, how-

ever, more variable than for males, perhaps as a result of the disturbing influence of the cyclic ovarian function. Therefore, when single determinations for many individuals are used to measure the variability, the total gives a larger net variability for females. It is as though we tried to compare the variability of stature in males and females under circumstances in which the measurement of height in the female was relatively unstable because of posture.

We may now turn to some consideration of observations other than those for normal persons. During the last two decades determinations of the basal metabolic rate as a clinical test have been made in many laboratories and upon thousands of individuals, and it is well established that it is a valuable test for disturbances of the thyroid gland because of its marked increase in hyperthyroid disease and its very low level in hypothyroidism or myxedema. It has at the same time become gradually recognized that the basal metabolic rate is of comparatively little value in the diagnosis of other conditions, in spite of the fact that, in a few, the basal metabolic rate may be definitely affected. The diseases other than those directly associated with the thyroid gland which are known to affect the basal metabolic rate directly or indirectly are the leukemias, the anemias, disorders of the pituitary and of the suprarenal glands, and a few other rare conditions. In addition, on account of respiratory distress, many cardiac patients may have elevated basal metabolic rates, on the other hand, extreme inanition lowers the basal metabolic rate.

During the 10-year period between 1917 and 1926 a large number of patients without thyroid disease were sent to the metabolism laboratory of The Mayo Clinic for the determination of their metabolism. For most of these patients the final clinical diagnosis was some condition which, from everything we know, did not characteristically affect the basal metabolic rate. After excluding, on the basis of a careful and detailed clinical examination, those patients having one of the diseases mentioned in the preceding paragraph which are known to affect the basal metabolic rate, we had for statistical study 7,117 females and 2,397 males, which group for brevity we have designated as the "non-metabolic disease group." In figure 2 is shown the distribution of the observations of the females in this group, and it is seen that the mean of this group is higher, but only by a small amount, 0.7 calories per square meter per hour (1.9 per cent of the standard mean), than a comparable group of normal individuals as judged by comparing them with The Mayo Foundation normal standard. The standard deviation of the distribution is somewhat larger than for a similar normal group, being 3.5 calories per square meter per hour (or 9.7 per cent of the standard mean) instead of 2.5 calories per square meter per hour (or 7 per cent of the standard mean) found for The Mayo Foundation standard. The distribution of the observations for these patients is seen to correspond to the Gaussian curve, as does that for strictly normal individuals. Observations

for the group of males are so similar that it is unnecessary to take space to reproduce the data graphically, the mean for the males is 0.6 calories per square meter per hour above a similar standard normal group (1.7 per cent of the standard mean), and the standard deviation is 3.8 calories per square meter per hour (10.4 per cent of the standard mean)

FIG 2 Distribution of basal metabolism for a group of non-metabolic diseases during a period of 10 years

The conclusion drawn from this phase of the study is that the largest group of sick individuals sent for a metabolism test, over half of them suffering from so-called chronic nervous exhaustion or neurasthenia, have a basal metabolic rate on the average very slightly higher (2 per cent), and that they have a greater variability (10 per cent), than strictly normal individuals (7 per cent). Using these round figures and remembering that for distributions following the Gaussian curve 95 per cent of the observations fall within ± 2 sigmas of the mean, we conclude that for such a group of patients, 95 per cent of the observations fall within -18 per cent and $+22$ per cent (2 per cent $\pm 2 \times 10$ per cent) on the usual B M R scale measured from The Mayo Foundation Standard.

Let us now give some attention to the pathologic conditions which we usually associate with disturbances of metabolism—typical disease of the thyroid gland. We consider them in three groups: (1) exophthalmic goiter, (2) adenomatous goiter, with and without clinical hyperthyroidism, and (3) spontaneous myxedema. Figure 3 gives the percentage frequency distribution for these disease groups on a single scale for comparison. The observations are shown in histogram form for the three diseases, comparison is made with a distribution for normal subjects which is represented by a smooth curve obtained from the data on which was based The Mayo Founda-

tion standard In contradistinction to the situation for the normal and non-metabolic disease group, the distributions of the basal metabolism in these thyroid disease groups are not symmetrical Gaussian curves but are

FIG 3 Basal metabolism in three thyroid diseases compared with group of normal individuals
Percentage frequency distribution for each group

“skew” (asymmetrical), the hyperthyroid group being skew in the positive and the hypothyroid in the negative direction That this skewness will have to be taken into consideration to determine the diagnostic significance to be attached to any given B M R determination which departs from the normal standard enough to be considered as possibly pathologic is manifest

For the exact calculation of the relative probability indicated by such a finding we will have to have a precise delineation of the frequency curves for the abnormals as well as the normals, a task we have not yet completed Moreover, for the calculation of the probability which a particular metabolism determination denotes, to be used as a criterion for decision in differential diagnosis, other elements enter besides the relative frequencies of the basal metabolism First among these perhaps are the relative frequencies of the diseases themselves During the 1917–1926 period referred to, in which there were seen 7,117 females constituting the non-metabolic disease group, there were 3,385 females with exophthalmic goiter, 3,693 with adenomatous goiter, and only 136 with myxedema The relative probability of any specific disease indicated by a given finding of metabolism will be in proportion to the actual numbers with this metabolism in this disease In figure 4 is shown the distribution of the actual frequencies for the various disease groups and for different values of metabolism as they were encountered in the metabolism laboratory during this period The total areas under each curve represent the total actual frequency of the individuals in

FIG 4 Comparison of normal distribution of basal metabolism with that for three groups of thyroid disease and a non-metabolic disease group. The frequencies are the number of cases corresponding to each group seen during a 10 year period. The total area under each curve is therefore proportional to the number of individuals in the corresponding group sent to the metabolism laboratory during this period.

the corresponding disease group, and the areas under the portion of the curves corresponding to any values of the metabolism give the relative frequencies and therefore probabilities of the diseases indicated by those values of metabolism.

This brief outline is not intended to be a complete analysis of the various questions touched on, but rather to present some ideas which a consideration of the variability of metabolism suggests. While even the precise study of the variability of metabolism of normal and different disease groups and its correlative probabilities will not in themselves make possible a precise differential diagnosis among metabolic and non-metabolic disease—indeed it will only corroborate the impression that clinical observation must play a large rôle here—such studies are not without importance for the diagnostic problems of the clinician.

It may be noted, though we do not wish to elaborate on the point at this time, that the entire curve for adenomatous goiter (with and without clinical hyperthyroidism) is well to the right of both that for the normal individuals and for the group with “non-metabolic diseases.”

In conclusion we wish to emphasize that it is important to study the distribution of cases in each disease group on the percentage basis (that is, on the assumption that one is as likely to encounter a patient with one disease as the other) in order to compare the characteristic basal metabolic findings in each disease. In addition it is equally important to take into consideration the relative frequency with which patients having different diseases present

themselves in a given clinic for study and differential diagnosis if one is to evaluate the probability of a given B M R indicating one or the other condition. This latter point is illustrated in figure 4, in which the graph is based on the actual number of cases occurring in each group in a given period and it is obvious that most of the patients sent to the metabolism laboratory of The Mayo Clinic, who have a B M R between -15 and -20 per cent *do not have mild myxedema*, but rather are normal individuals so far as their metabolic rate is concerned, if, however, as in figure 3, the comparison is made on the assumption, which of course is contrary to the fact, that the number of cases of myxedema is equal to those in the other groups, then it appears as though it were nearly an even chance that an individual with a B M R between -15 and -20 per cent might have myxedema. On the other hand, if the proportion of patients in different disease groups is not very dissimilar, essentially similar deductions will be made whether the frequency is plotted on a percentage basis or on the actual number of cases. For example, the graphs in both figure 3 and figure 4 show that there are many patients with adenomatous goiter who have a B M R between $+15$ and $+20$ per cent, while only relatively few patients who have exophthalmic goiter have a B M R between $+15$ and $+20$ per cent.

Finally it must be recognized that "basal metabolism" as an actual observation, under any defined standard condition, is variable, like any biologic observation, and in consequence no one *lowest* metabolism has a prerogative to be considered *the* basal metabolism over any other measurement made under the defined conditions.

CARDIAC HYPERTROPHY. ITS RELATION TO CORONARY ARTERIOSCLEROSIS AND CONGESTIVE HEART FAILURE*

By DAVID DAVIS, M D, and HERRMAN L BLUMGART, M D,
Boston, Massachusetts

THE cause of hypertrophy of the heart has aroused the interest of pathologists and clinicians for more than three centuries. The hypertrophy of skeletal muscle after increased effort led to the belief that, similarly, cardiac muscle hypertrophied because of increased work. Hypertrophy of the left ventricle in patients with hypertension or aortic insufficiency, and hypertrophy of the right ventricle in pulmonary stenosis or tricuspid valvular disease lent plausibility to this theory.

Certain phenomena, however, associated with hypertrophy of the cardiac musculature have not been readily explicable on the basis of the above hypothesis of increased cardiac work. In animals in which experimental valvular lesions were produced such as aortic insufficiency, increased work of the heart undoubtedly led to hypertrophy, but the degree of hypertrophy occurring even in the most successful experimental instances was much less than that observed clinically in similar lesions¹¹. That cardiac hypertrophy is not due solely to increased work is also suggested by the lack of relationship between the degree of valvular obstruction and the degree of hypertrophy seen in man. These considerations have led observers in the past to consider the possible influence of other factors in the production of hypertrophy.

It appeared from analysis of the literature that the significance of nutritional effects had not been fully established. It seemed to us that more information bearing on this phase of the problem might be obtained by ascertaining in a consecutive series of patients whether those hearts which showed advanced arteriosclerosis differed in weight from those showing little or no such change. No case was included in the series that showed evidences of hypertension, syphilis, rheumatic heart disease, anemia, or other factors which would give rise to increased work on the part of the heart. Patients who had congestive failure associated with advanced coronary sclerosis were considered in a separate group in order to study the importance of congestive failure itself in the production of hypertrophy.

The purpose of this communication is to present the results of this study.

* Received for publication August 31, 1937.

and to appraise the significance of two factors in the causation of cardiac hypertrophy (1) a diminished coronary circulation, (2) the influence of chronic congestive heart failure

METHODS AND RESULTS

To evaluate the rôle of coronary artery disease in producing hypertrophy of the heart, the cardiac weights of an unselected consecutive series of patients that had come to postmortem examination were studied. To learn the significance of a diminished coronary circulation uncomplicated by other factors, all cases with any antemortem evidence of congestive failure and all cases showing signs or symptoms of conditions acknowledged to be of possible significance in the production of cardiac hypertrophy such as hypertension, valvular heart disease, mediastino-pericarditis, long continued anemia, leukemia, or thyrotoxicosis were eliminated. Hearts showing slight degrees of aortic stenosis of arteriosclerotic origin were also excluded. To rule out the existence at any previous time of arterial hypertension is always difficult since the fluctuations in blood pressure in this condition always render it theoretically possible that the blood pressure may have been elevated prior to the first recorded physical examination or between the various examinations listed. In order to minimize this possible error, the past history was carefully investigated in each case and the blood pressure measurements obtained on previous admissions in other hospitals, by outside physicians and by life insurance examinations were considered. The upper limit of normal blood pressure was taken as 160 mm mercury systolic and 90 mm mercury diastolic. The blood pressure data obtained during a final illness were considered with reservations. Cases in which death was associated with shock due to acute coronary occlusion, intestinal obstruction, perforation of a viscus, or hemorrhage were, of course, excluded unless evidence of a normal blood pressure prior to the final illness was available.

The heart weights of a consecutive group with advanced coronary disease were then compared with a similarly consecutive group showing little or no coronary disease, all cases with the above mentioned factors that might produce cardiac hypertrophy having been eliminated. The only error inherent in this separation of the two groups would be that of possibly overlooking involvement of a portion of some coronary branch, this error would lead to the false inclusion of some cases in the group with little atherosclerosis and so make any differences between the two groups less striking.

In classifying the degree of atherosclerotic involvement of the coronary vessels, the following criteria were employed: grade I, all large branches free from atheromatous changes, grade II, scattered atheromata but no ulcerations or striking changes in the surface of the intima, grade III, the intima covered with atheromatous plaques and inclusion in the pathological report of a definite statement by the examining pathologist to the effect that

there was no narrowing of the lumen at any point, grade IV, as in grade III with one or two sites of slight narrowing, grade V, as in grade IV but with greater degree of narrowing, grade VI, complete obliteration of one major coronary branch such as the left anterior descending, left circumflex or right coronary with little or no narrowing of other branches, and grade VII, complete obliteration of one branch but with marked changes and narrowing in another or all coronary branches

Figure 1 shows the distribution of cardiac weights in 31 consecutive subjects with advanced coronary disease (grades IV–VII) as compared with 38 cases showing little coronary disease (grades I and II). The ages in the group with marked coronary arteriosclerosis varied from 49 to 80 years and averaged 62 years, in the patients with little arteriosclerosis the ages varied from 50 to 76 years and averaged 61 years, nine of the former

FIG 1 Comparison of heart weights in patients with advanced coronary sclerosis with those showing little or no coronary sclerosis

group and 14 of the latter group were females (Table 1). Of the 31 hearts showing advanced coronary arteriosclerosis, eight were classified as grade VII, six, grade VI, fifteen, grade V, and two, grade IV. Nine of the 31 cases died of coronary thrombosis. Of the 38 hearts showing but little coronary arteriosclerosis, 26 were classified as grade I, 12 as grade II

TABLE I

Data in Series of Patients with Little or No Coronary Arteriosclerotic Heart Disease

| No | Age | Sex | Ht Wt Gm | Degree Coronary Disease | Blood Pressure at Final Illness | | Cause of Death |
|----|-----|-----|----------------|-------------------------------|------------------------------------|--------------|-----------------------------|
| | | | | | Systolic | Diastolic | |

The range of distribution of cardiac weights of the cases with advanced coronary arteriosclerosis was definitely higher and the average weight was 348 grams. The mean heart weight of the cases with little coronary atherosclerosis was 275 grams. Although the group with marked coronary arteriosclerosis showed a higher weight distribution, there were few very heavy hearts, the heaviest weighed 440 grams and only six weighed more than 400 grams. Blood pressures taken a few months to two years prior to the final illness were obtained in cases 30, 28, and 20 to 26 inclusive. The pressures varied from 110 to 142 mm systolic and from 60 to 80 mm diastolic. The blood pressures in the remaining three cases with heart

weights above 350 gm were obtained soon after admission to the hospital before the terminal stages of the illness, in two of these latter three instances the history recorded that previous examinations showed no evidence of an elevated blood pressure

To determine the influence of congestive failure in the production of cardiac hypertrophy, a consecutive series of necropsy reports of patients in whom congestive heart failure had occurred before death were examined. Cases in which hypertension, valvular disease, mediastino-pericarditis, or any of the other accepted causes of cardiac hypertrophy had been present were excluded. A series of 17 cases remained for study, 15 of which showed advanced coronary arteriosclerosis, falling in groups V to VII above (table 3). The cardiac weights of this series were compared with the previously mentioned series of cases showing advanced coronary atherosclerosis but no congestive failure (figure 2). The higher incidence of

greater heart weights in cases with congestive failure is striking (figure 2) With but one exception, the cases with congestive failure showed cardiac weights of 400 grams or over, 11 being 500 grams or over Of the latter 11, five were 600 grams or over These findings are in contrast with those in the group with advanced coronary atherosclerosis but no congestive failure

FIG 2 Cardiac weights in patients with advanced coronary disease compared with heart weights in patients with congestive failure

in which no cardiac weight above 440 grams was observed. In addition to the data presented above, the progressive increase in heart size could be followed by frequent roentgenograms in two patients with recurrent attacks of congestive failure due to coronary atherosclerosis who eventually came to postmortem examination.

CASE REPORTS

Case 1 (L. S.) This male, aged 63, had had angina pectoris for seven and a half years, and during the past year was admitted to the hospital three times for congestive failure. On his first admission on December 10, 1935, he complained of palpitation, dyspnea on exertion, cough and nocturnal dyspnea of two months' duration. Physical examination showed cardiac enlargement, gallop rhythm, râles at both bases, an enlarged tender liver, and edema of the legs and over the sacrum. A seven foot roentgenogram taken in the out-patient clinic on June 4, 1929, showed a transverse cardiac diameter of 14.7 cm (table 4). A second roentgenogram taken on November

13, 1934, showed a transverse diameter of 13.7 cm. Thus, there had been no change in the cardiac measurements during a period of five years. Just prior to this admission to the hospital, however, the roentgenogram showed a transverse cardiac diameter of 18.5 cm, an appreciable increase presumably in part due to acute dilatation accompanying the congestive failure. Seven days after this admission he was discharged improved, but a few months later, March 30, 1936, he was readmitted for congestive failure and remained in the hospital for 14 days. Eight months later, January 14, 1937, he was admitted a third time for congestive failure. At the end of the first week he was free of edema and allowed to be up and about the wards. A seven foot roentgenogram was then taken on February 2, 1937, and this showed a transverse diameter of 19.6 cm. The increase in cardiac size during the past year was greater than apparent from the roentgenographic measurements, for the increased transverse diameter of 18.5 cm the year before was associated with congestive failure presumably associated with some acute dilatation. He died suddenly on February 3, 1937, and postmortem examination revealed no cardiac dilatation. The heart weighed

500 grams The coronary distribution was studied with injection and roentgenographic methods by Dr Monroe Schlesinger and found to be the seat of extensive coronary sclerosis and occlusion A tremendous collateral circulation had developed The changes in heart size are recorded in table 3 and figure 3 The cardiac size showed a progressive increase during the period of congestive failure

FIG 3 Case 1 Increase in heart size in course of congestive heart failure

Case 2 (H B) This male, aged 57, was admitted to the hospital on March 8, 1930, complaining of dyspnea on slight exertion and edema of the ankles of two weeks' duration Examination showed cardiac enlargement and auricular fibrillation, and the electrocardiogram showed bundle branch block In the course of the next three years with the exception of a few months he was not free from congestive failure and was almost completely confined to bed Transverse diameters of subsequent seven foot roentgenograms showed a progressive increase in heart size (table 3) Necropsy on January 26, 1934, showed evidence of an old mitral lesion with calcification of the mitral ring, thickening and some retraction of the valve cusps There was, however, no appreciable incompetency of the valves The slight mitral lesion had undoubtedly been present for many years, and therefore it probably did not have any influence on the cardiac enlargement during his recent illness The coronary arteries showed an extreme degree of sclerosis with numerous points of occlusion The heart weight was 735 grams Figure 4 shows the increase in size in the course of heart failure

FIG 4 Case 2 Increase in heart size in course of congestive heart failure.

DISCUSSION

The foregoing results do not solve the problem of cardiac hypertrophy but are of value in appraising the etiological importance of two contributory influences, coronary arteriosclerosis and congestive failure, which are frequently operative but often neglected in discussions on the subject. The early studies of Corvisart in 1806,³⁵ and the emphatic views of Cohnheim³⁶ in 1882, as well as the supporting opinions of many later investigators, have stressed increased work as the stimulus causing hypertrophy of the cardiac musculature. Clinical experience, as well as many experimental investigations, has thrown doubt, however, upon the validity of the view that cardiac hypertrophy can always be ascribed entirely to increased work. Practically all investigators agree that cardiac hypertrophy is found under conditions demanding increased work of the heart but many observers have stated that various other factors may play a contributory or even a dominant rôle, their views may be conveniently grouped under the following headings:

1 *Elevated Metabolism* In thyrotoxicosis the heart weight has been found increased by numerous observers. This increase may be due (1) to coincident marked cardiovascular disease or latent heart disease made manifest by the hyperthyroidism, (2) to overwork consequent to the elevated metabolic rate, or (3) to a specific toxic effect on the heart. Only in the latter two instances can the hypertrophy be ascribed to the thyroid disease itself. Failure to evaluate coincident organic disease has vitiated many of the reports on this subject and has led to varied opinions^{13, 27}. An analysis of the available data indicates that cardiac hypertrophy occurs only infrequently in uncomplicated thyrotoxicosis and then only to a slight degree^{21, 22}. Experimentally, cardiac hypertrophy has been produced by the administration of thyroid, but the conditions of the experiments and the criteria of hypertrophy employed do not permit unquestionable clinical application of the results^{23, 24, 25, 26}. In chronic lymphatic leukemia in which there is an elevated metabolic rate unassociated with hyperthyroidism, post mortem examination has revealed the average heart weight increased 75 grams above the normal¹⁶. It is of interest that in frizzle fowl in which species the metabolism is elevated, the hearts are reported as definitely hypertrophied^{3, 4}.

2 *Increased Physical Exertion* There is a divergence of opinion regarding the effect of exercise on the weight of the heart, some maintaining that the heart weights of athletes fall within the range of normal for individuals of the same size and age who have not engaged in prolonged strenuous exercise, while others believe that prolonged exercise leads to definite hypertrophy. In accord with this latter view Tung and his co-workers²⁰ state that definite cardiac enlargement of the heart as seen by roentgen-ray was found in 45 per cent of their series of 46 ricksha pullers, no heart weights, however, are given. Steinhaus²⁹ has discussed this aspect of the problem in detail.

3 *Anemia* Cardiac hypertrophy at post mortem has been found in pernicious anemia in the absence of other factors to account for it⁵ Similarly, Porter¹⁷ by roentgenographic studies found an increased heart size in the anemia associated with hookworm disease and obtained suggestive evidence of hypertrophy, inasmuch as the heart size, while becoming smaller after alleviation of the anemia, did not return to normal

4 *Coronary Arteriosclerosis* Miller and Weiss¹⁵ reported 19 cases with advanced arteriosclerotic involvement of the coronary vessels unassociated, however, with any evidence of cardiac hypertrophy, leading them to the conclusion that advanced coronary artery disease does not necessarily cause gross cardiac hypertrophy The cardiac weights in two instances were, however, 350 and 400 grams Similarly, Horine and Weiss¹² found no roentgenological evidence of cardiac enlargement in 20 patients with coronary thrombosis observed by periodic seven foot roentgenograms from five months to nine years after the initial attack It is not likely that small changes in heart weight would be readily translated into changes in the seven foot roentgenogram Bartels and Smith,¹ on the other hand, in a study of patients with myocardial infarction found heart weights of 400 grams or more in 26 of 42 patients, the largest heart weighing 715 grams These authors stated that in none of these 42 cases was there any evidence of any condition commonly supposed to produce hypertrophy No statement is made, however, regarding the presence or absence of congestive failure Nemet and Gross¹⁸ in their study of the inter-relationship of arteriosclerotic heart disease and chronic congestive failure report 11 patients of their series of 100 who showed no evidence of congestive failure Of these 11 cases, seven showed heart weights less than 400 grams, two were above 400 grams and two showed generalized microscopic hypertrophy of muscle fibers Coronary artery disease sufficiently marked to cause coronary thrombosis was found to be the sole factor in producing cardiac enlargement in only 11 of a series of 128 patients with enlarged hearts reported by Parkinson¹⁹

5 *Other Defective Nutritional States* Cardiac hypertrophy has been observed experimentally after the injection of spartein sulphate and adrenaline chloride⁷ In two cases in the literature in which the left coronary artery arose from the pulmonary conus^{2,6} marked left ventricular hypertrophy was found in the absence of valvular defects, the supply by the left coronary artery of venous blood under the decreased pulmonary arterial pressure was evidently the causal factor That cardiac enlargement might be due to defective nutrition of the heart muscle because of deficient coronary blood supply consequent to the fall of mean arterial pressure was advanced as a cause of hypertrophy by Lewis and Drury³¹ in their study of the pathological physiology of arteriovenous aneurysm These authors further stated that defective nutrition is probably the cause or contributing cause of cardiac hypertrophy in such conditions as aortic regurgitation, coronary arteriosclerosis, anemia or any condition in which the output of the heart is

decreased or the mean arterial pressure is much reduced Willius and Smith³² report hypertrophy of the heart in several children who survived for only short periods following their first rheumatic infections and in whom inflammatory lesions of the heart were widespread Willius and Smith conclude that the severe myocarditis of these children was the chief factor contributing to the production of cardiac hypertrophy, since the valvular deformity was relatively slight The coexistence of congestive heart failure in at least three of these four cases makes interpretation of their findings difficult Myocardial degeneration due to unknown causes has been found in cases of marked idiopathic hypertrophy of the heart¹⁴

6 *The "Injury Theory" of Cardiac Hypertrophy* Among the numerous other theories to account for cardiac hypertrophy, that first enunciated by Horvath,²⁸ later supported by the pathological studies of Albrecht³³ and more recently strengthened by the important experimental observations of Eyster^{8, 9, 10} seems most satisfactory, since it provides a common denominator according to which practically all forms of hypertrophy become understandable Horvath²⁸ strenuously objected to the work theory of hypertrophy and asserted that the fundamental cause of hypertrophy of any muscle from whatever stimulus lay in stretching of muscle fibers greater than normal This stretching acts as a common causal factor of both work and of hypertrophy, the latter two being results and in no way interrelated as cause and effect He stated that the uterus hypertrophies without work during pregnancy and that the eye muscles and diaphragm accomplish much work but are not under tension and do not hypertrophy Albrecht³³ described histologic evidences of muscle injury preceding hypertrophy, and stated that interference with the normal nutrition of the heart preceded hypertrophy The experimental observations of Eyster and his associates^{8, 9, 10} are of considerable importance These investigators produced aortic regurgitation in dogs, following which roentgenograms showed definite acute dilatation of the heart, reaching its maximum on the third to sixth day and disappearing by the tenth day Subsequently, hypertrophy gradually developed Similar dilatation and subsequent hypertrophy were induced by creating aortic stenosis by constriction of the ascending aorta with a rubber band In one group of animals the band was removed after from three to six days when dilatation had reached its maximum and before hypertrophy had occurred The hearts subsequently hypertrophied to an extent comparable to that occurring in the dogs in which the bands were allowed to remain intact During the period of initial dilatation the muscle wall was thin and stretched, and hydropic degeneration became evident After hypertrophy had developed there was an increase in size of the individual fibers without increase in fibrous tissue The hypertrophy was therefore considered to be a reaction to injury brought about by the sudden dilatation

The above theory as to the cause of hypertrophy was termed by Eyster⁸

the "theory of injury" and would seem to provide a common denominator for most of the various types of hypertrophy. Thus, any condition which imposes an increased initial tension on cardiac muscle such as hypertension, valvular defects, or congenital defects is in accord with this theory. Hypertrophy in conditions in which prolonged impaired nutrition of the heart muscle exists is likewise readily understandable for the consequent dilatation or stretching again acts as the causal factor. The experimental studies of hypertrophy following inflammation or the injection of toxins, the occurrence of hypertrophy in leukemia and pernicious anemia, the left ventricular hypertrophy in some instances of so-called idiopathic hypertrophy in which the left coronary artery carries venous blood at lower pressures because of its anomalous origin from the pulmonary artery are instances which are in accord with this concept.

Our own observations presented in this communication provide strong clinical support to the "injury theory" of Horvath, Albrecht and Eyster as well as affording insight regarding the degree to which hypertrophy of the heart may be ascribed to coronary arteriosclerosis itself. The fact that the group of patients with moderate or advanced arteriosclerosis were similar in all other respects, such as age, clinical condition, etc., to the group with slight or no coronary arteriosclerosis permits one to conclude that slight or even moderate cardiac hypertrophy is frequently, though not necessarily, associated with the more advanced degrees of arteriosclerotic involvement of the coronary arteries. The occurrence of cardiac hypertrophy in many conditions in which the work of the heart is increased makes it difficult to ascertain the degree to which other factors are operative in the production of the hypertrophy, in the patients described above, conditions requiring increased work by the heart were not present.

It is reasonable to infer on the basis of the involvement of the coronary vessels and the presence of diffuse focal changes noted in such hearts that the nutrition of the musculature is impaired. Dilatation or stretching of the fibers under such circumstances leads to subsequent hypertrophy, when the degree of impairment is greater, more marked consequences ensue and congestive failure supervenes. As shown by Starling and his associates,³⁴ such dilatation is in the nature of a beneficial response since it enables the heart for the moment to increase its capacity for work. The fact that all patients with considerable coronary arteriosclerotic involvement do not show hypertrophy is probably due to the development of adequate collateral circulation which compensates in such cases for the localized diminished blood supply.

Our data also indicate that the existence of congestive failure in itself leads to the development of hypertrophy. It has often been inferred that the largest hearts in congestive failure were enlarged initially and fail because of the previous dilatation and hypertrophy. According to this concept, congestive heart failure is the failure of the hypertrophied heart. If this were so, one would expect to find such large hearts before the onset of

failure in at least a few instances in an unselected group of patients with advanced coronary arteriosclerosis. Slightly increased weights were observed by us in this group (table 1) but the degree of hypertrophy was never great.

In brief, our data indicate that with the lesser degrees of coronary arteriosclerosis the heart undergoes little or no hypertrophy, with more severe involvement a slight degree of hypertrophy is encountered presumably due to impaired nutrition of the muscle fibers causing them to undergo stretching and consequent hypertrophy. In patients who have suffered from congestive failure the weights of the hearts are considerably increased. This finding might be interpreted as being the direct result of more advanced degrees of arteriosclerotic involvement of the heart, the concomitant congestive failure playing no significant rôle. Our data, however, suggest that while the advent of congestive failure may be due to severe impairment of nutrition, the more striking degrees of cardiac hypertrophy observed in such patients are largely consequent to the development of congestive failure itself and rarely occur in its absence. In accord with this concept, the degree of cardiac hypertrophy seemed generally proportional to the severity and duration of congestive failure.

SUMMARY AND CONCLUSIONS

The purpose of this communication is to present the results of the findings in patients with various degrees of coronary arteriosclerosis in order to appraise the significance of two factors in the causation of cardiac hypertrophy: (1) a diminished coronary circulation, (2) the influence of chronic congestive failure.

The cardiac weights of a consecutive series of patients were studied to learn whether those hearts which showed advanced arteriosclerosis differed from those showing little or no such change. No case was included that showed evidences of hypertension, syphilis, rheumatic heart disease, anemia, or other factors which would give rise to increased work on the part of the heart.

The cardiac weights of the cases with advanced arteriosclerosis showed a definitely higher range of distribution than the cases in a comparable series with but little coronary arteriosclerosis. There were, however, few greatly hypertrophied hearts in the cases showing advanced coronary arteriosclerosis, the heaviest weighing 440 grams and only six of the 31 weighing more than 400 grams. In a comparable series of patients in whom congestive failure was also present, 16 out of 17 showed heart weights above 400 grams and eleven above 500 grams.

The data indicate that with the lesser degrees of coronary arteriosclerosis the heart undergoes little or no hypertrophy, with more severe involvement a slight or moderate degree of hypertrophy is encountered presumably due to impaired nutrition of the muscle fibers which causes them to undergo

stretching and consequent hypertrophy. In patients who have suffered from congestive failure, the weights of the hearts are considerably increased.

These results support the "injury theory" of Horvath, Albrecht, and Eyster of the causation of cardiac hypertrophy rather than the widely held "work hypertrophy theory."

EFFECT OF VITAMIN C ON THE CULTURE OF H_{37} TUBERCLE BACILLUS*

By FRED H. HEISE, and WM. STEENKEN, JR., *Trudeau, New York*

MANY infectious diseases have been shown to be accompanied by a subnormal urinary excretion of cevitamic acid—vitamin C. Presumably the cevitamic acid has been altered or destroyed, directly or indirectly, by the action of the infecting organisms. That this may be true is shown by the development of scurvy in spite of ample gastrointestinal intake of cevitamic acid in the food. Marin¹ reports such an instance and thinks the destruction of the vitamin was due to *Bacillus coli* or paratyphoid B in the intestine. His patient failed to recover by oral anti-scorbutic treatment. Steppe² showed this destruction of vitamin C experimentally. He found that various types of coli and paratyphoid react differently on vitamin C under the same cultural conditions. The pH apparently had no influence. Some of the organisms destroyed the vitamin in 24 hours. On the other hand, the vitamin has a definite influence on some bacteria and upon bacterial and other toxins. It will not, however, replace the growth promoting substances found in some media (Koser et al.³). Von Gagyi⁴ studied the effect of various organisms upon vitamin C and the effect of vitamin C upon the same organisms. He worked with coli communis, paracoli, typhoid, paratyphoid, dysentery, saprophytes and the tubercle bacillus. He found that the tubercle bacillus lived at least 70 hours upon media containing five parts cevitamic acid per 1,000. A change in virulence of these tubercle bacilli was not determined up to the time of his publication. Boissevain and Spillane⁵ found that growth of H_{37} tubercle bacilli occurred only after the cevitamic acid content had fallen below 0.001 per cent. The synthetic cevitamic acid content of the medium was kept more or less constant by the addition of cevitamic acid every three days. Although when this was done the pH was within the range of growth, no growth took place when the concentration of the vitamin was 0.001 per cent or higher. However, no protective action against H_{37} was produced in guinea pigs by the administration of 50 times the antiscorbutic dose of cevitamic acid. This confirmed the work of others who failed to find such a protective action.

In a series of experiments with cevitamic acid given by vein, Heise, Martin and Schwartz⁶ found that the sensitivity to tuberculin was lessened and the blood sedimentation speed reduced in a proportion of tuberculous patients, although Heise and Martin⁷ could demonstrate no protective action.

of cevitamic acid against tuberculous infection in guinea pigs, in a preliminary test. Interest was naturally aroused as to the possible effect of cevitamic acid upon the growth of the tubercle bacillus upon a medium of known content.

EXPERIMENTAL PROCEDURE

Twenty cc of Proskauer and Beck's synthetic medium were placed in each of four flasks. To two of them 100 mg of cevitamic acid were added. The H₃₇Rv (Steenken) variant of tubercle bacilli was seeded into the bottom of the medium in each flask. Growth was much more abundant in the

FIG 1

control flasks. Daily subcultures were made for the first four days and subsequently every third day for five weeks upon slants of Hohn's medium—pH 6.5. Abundant growth appeared on subcultures of the controls within eight days but the subcultures from the cevitamic acid cultures developed only a few colonies and showed a growth lag three to five times as long as in the controls. After ten days growth developed more rapidly than previously in all cevitamic acid cultures and in the subcultures. All transplants to Hohn's medium were further subcultured on the same medium to determine whether there were differences in growth characteristics. None was noted after 40 days.

VIRULENCE

Four guinea pigs were inoculated intratesticularly with some of the less typical deepseated growth from the cevitamic acid flasks. All of the pigs reacted, intradermally, to 5 per cent O.T. two weeks after inoculation. Death from generalized tuberculosis occurred in all four pigs within 90

days Growing colonies from two of the Hohn's medium subcultures of the cevitic acid flasks were inoculated into guinea pigs The colonies were isolated and raised somewhat in structure About 30,000 bacilli, dry weight, from each of two colonies that had different structure than the parent colony were inoculated into two pigs These pigs were controlled with the inoculation of two pigs with a typical parent colony All four pigs reacted intradermally to 5 per cent O T two weeks after inoculation Death from generalized tuberculosis occurred also in these four pigs within 90 days

To discover whether the lag period noticed in the previous experiments was due to the reaction of the medium, another experiment was performed To each of two flasks containing 20 c c of synthetic medium, 100 mg of partially neutralized cevitic acid were added The flasks were incubated at 37.5° C for five days Small portions of the medium were removed for titration with sodium 2, 6-Dichloro-Benzenone-endo-3-chlorophenol (Eastman) from time to time and it was found that no unchanged cevitic acid remained after seven days The color of the medium was then a burgundy The contents of each flask were then neutralized with N/10 NaOH until the pH corresponded with that of the medium in two control flasks, viz, pH 7.2 H₃₇ Rv variant was floated on the surface of the medium in all four of the flasks, two containing reduced cevitic acid and two controls Growth was slower in the presence of reduced cevitic acid than on the controls Growth characteristics and microscopic morphology were the same in all flasks Animal inoculations were not made

The above experiment was repeated but instead of allowing the cevitic acid to become entirely changed, 100 mg of the partially neutralized acid were added to the two experimental flasks every third day (Previous determinations had shown the rate of change in the synthetic medium used, see table) Such additions were carried out for a period of nine days—a total of 300 mg At this time a marked difference in the growth characteristics was noted in the two cevitic acid flasks as compared to the controls Growth was denser and less spreading in the cevitic acid flasks It appeared as small raised islands with but little of the veil-like intervening growth which characterized that in the control flasks The cevitic acid medium growth resembled that of an Ra variant rather than an Rv variant Changes in the reaction of the medium* as noted in the table were too slight to have accounted for the variations in growth

The experiment of growing the bacilli in the constant presence of cevitic acid was carried out in another way The Rv variant was floated on the medium and then subcultured on similar medium every third day The controls were treated likewise Two thousand one hundred mg of cevitic acid were used Again the growth resembled that of an Ra rather than an Rv variant as appeared in the controls On the cevitic acid

*We are indebted to Dr Eric Alling for making pH determinations with a glass electrode

medium the growth appeared as an elevated island without a veil-like periphery, whereas on the controls the growth was flat, veil-like and extended up the sides of the flasks

VIRULENCE TESTS

Four guinea pigs were inoculated intracerebrally, two with approximately 2,500 organisms, dry weight, from the cevitic acid culture and two with the same dose from the control cultures. All four pigs reacted to 5 per cent O T intradermally two weeks after inoculation and died of tuberculosis of the brain within 34 days.

Six other pigs were inoculated subcutaneously with about 5,000 organisms, three from the cevitic acid cultures and three from the control flasks. No change in virulence was noted at autopsy.

SUMMARY

The addition of cevitic acid to Proskauer and Beck's synthetic medium alters the character of the growth of tubercle bacilli floated on it. On this medium Rv variants of the H₃₇ strain develop like Ra variants whereas in control broth without cevitic acid the growth retains its Rv characteristics. There is no associated alteration in the virulence of the organisms.

Note The cevitic acid used in these experiments was donated by Merck and Company, Rahway, N J.

CASE REPORT

CONGENITAL DISPLACEMENT OF THE TRICUSPID VALVE (EBSTEIN'S DISEASE) REVIEW AND REPORT OF A CASE WITH ELECTROCARDIOGRAPHIC ABNORMALITIES AND DETAILED HISTOLOGIC STUDY OF THE CONDUCTION SYSTEM

By WALLACE M. YATLER, M.D., F.A.C.P., *Washington, D. C.*, and
MORSE J. SHAPIRO, M.D., *Minneapolis, Minnesota*

CONGENITAL anomalies of the tricuspid valve unassociated with other major cardiac malformations are rare. However, there may be atresia of the valve, with or without stenosis of the right venous ostium, only one or two leaflets, or as many as four, five or six leaflets, excessive development of the valve with atresia of one leaflet, an extra leaflet fused with one of the normal leaflets, congenital neoplastic hyperplasia of the valve, displacement of the valve downward into the right ventricle, or even transposition of the tricuspid and mitral valves. Herxheimer¹ (1909-1913) reviewed briefly the reported cases of such anomalies, which, of course, have been augmented since his study. In 1866 Ebstein² described the first definite case of congenital displacement of the tricuspid valve, and since that time at least 14 essentially similar cases have been recorded, making, with the new case described in this report, a total of 16 certain cases in the literature.

REVIEW OF THE LITERATURE

Ebstein's patient (1866) was a man of 19 years who had had dyspnea and palpitation of the heart since childhood. For two years before death he had had a productive cough. For 16 days before death he had presented symptoms and signs of heart failure with tricuspid regurgitation, as well as manifestations of tuberculous pneumonitis. The heart was greatly enlarged. There was a forceful pulsation and a thrill over the precordium. A long murmur, beginning in systole but running through diastole and obscuring the heart sounds, was heard best at the base of the heart, on the right side, and also in the back. The second pulmonic sound was not accentuated. At necropsy the right auricle was found to be hypertrophied and widely dilated. The Thebesian valve was absent. The foramen ovale was not completely closed and the flap contained several fenestrae, one quite large. In the large right ventricle was seen a large membrane springing from part of the annulus fibrosus, the anterior and posterior walls of the ventricle and partly in its posterior and inferior half from the interventricular septum. Its external and under surface was attached to the anterior and lower wall of the ventricle by chordae tendineae and papillary muscles. This repre-

sented the fused and downwardly displaced anterior and posterior leaflets of the tricuspid valve. The membrane was white and glistening and fenestrated, especially in its lower half. These fenestra opened into a space between the outer surface of the membrane and the wall of the ventricle. About 15 mm below the annulus fibrosus a small flap arose from the endocardium of the interventricular septum with its base above and its apex below, whose edge was attached by chordae tendineae to the endocardium. This represented the isolated and malformed septal or medial leaflet of the tricuspid valve. It formed, with the anterior portion of the large membrane, an oval opening measuring 4 by 3 cm into the conus arteriosus. The right ventricle was greatly dilated. The left auricle and ventricle were normal. The malformation of the heart, therefore, consisted mainly of an anomalously formed and downwardly displaced tricuspid valve which divided the right side of the heart into a large auricular portion consisting of the true auricle and the greater part of the ventricle and a smaller ventricular portion consisting of the lower portion of the true ventricular cavity and the pulmonary conus. During ventricular systole part of the blood in the latter ventricular portion undoubtedly ejected blood both into the pulmonary artery and back into the auricular portion. Until the time of the terminal heart failure the excess blood in the auricular portion probably passed through the patent foramen ovale, thus preventing positive venous pulsation and passive congestion of the viscera. Ebstein explained the murmur as being due in its systolic component to blood rushing back into the right auricle and venae cavae and in its diastolic component to the blood streaming into the cavity of the ventricle over the surface of the not entirely smooth membrane. Besides the cardiac findings the necropsy revealed active and advanced pulmonary tuberculosis and congestion of the viscera.

Marxsen³ described the next case of this cardiac anomaly in 1886. The patient, a woman aged 61 years, developed profuse diarrhea with a high fever and rapid pulse rate after the extraction of a mature cataract. At necropsy the cardiac findings were apparently unexpected, and there was no passive congestion of the viscera. Death had been due to ulcerative colitis. The right side of the heart was very large, the left small. There was thickening of the mitral valve. The tricuspid valve was represented by a pouch-like membrane composed of three indistinctly differentiated and fused components. The membrane was attached to the wall of the ventricle much as in Ebstein's case, but the septal component was not isolated but was fused with the anterior component. The posterior component was attached vertically downward along the interventricular septum, the very large anterior component to the anterior wall of the ventricle. There were numerous small chordae tendineae holding the edges of the valve down to the wall of the ventricle and the moderator band without the intervention of true papillary muscles. The largest component was almost fused to the wall of the ventricle. The valve opened into the pulmonary conus through an aperture 3 cm in diameter. The foramen ovale was patent, and the Eustachian valve was well developed. The pulmonary conus was broad and hypertrophied.

MacCallum's⁴ case (1900) was similar. The patient was a man who had always been blue and who died at the age of 30 years of pulmonary tuberculosis. At the necropsy there was found chronic tuberculosis of the lungs and chronic passive congestion of the viscera. The heart was enlarged, especially the right side. The Eustachian valve was persistent as a large apparently functional

valve The valvula foraminis ovalis also persisted but was not competent to close the foramen ovale, which was open to a width of about 1 cm The very large appendix auriculæ opened by two mouths into the auricle which was somewhat constricted near its middle by a muscular ring The tricuspid valves were ballooned out into the right ventricle and had apparently become closely grown together with the ventricular wall Two of the segments were visible against the interventricular septum and toward the left as wrinkled, folded membranes, which were very soon fused with the ventricular wall and were apparently functionless The remaining membrane seemed to furnish the whole membrane which lined the ventricular wall and septum and which below, roofing the trabeculae, formed the floor of a sort of intervalvular chamber The latter opened into the ventricle through a round orifice situated toward the left just below the conus arteriosus and guarded by a flap-like fold of the chamber wall It further opened through several small fenestra, each guarded by tiny valves which were furnished with chordae tendineae and papillary muscles The pulmonary artery was slightly narrowed, and the ductus arteriosus persisted as a cord, but otherwise the heart was approximately normal

Schonenberger's⁵ case (1903) was that of a girl four and a half years old who was found to have cyanosis and clubbed fingers There was an intense thrill over the precordium, and systolic and diastolic murmurs replaced the heart sounds The area of cardiac dullness was greatly increased to the right, and bronchial breath sounds were heard over the right lung Death occurred suddenly At necropsy the heart was found to fill nearly the whole of the right hemithorax, and the right lung was thin, indurated and almost completely calcified The wall of the right ventricle appeared to be a thin membrane distended with blood The left ventricle was very small with firm thick walls, a thickened endocardium and numerous chordae tendineae between the papillary muscles The pulmonary artery was small compared to the aorta The auricles were very large A large membrane resembling a sail hung down in the right ventricle as in Ebstein's case and apparently represented the fused anterior and posterior components of the tricuspid valve There was an exaggerated moderator band between the conus arteriosus and the remainder of the right ventricle from which arose a papillary muscle with chordae tendineae attached to the large membrane and to the upper part of the conus arteriosus near the pulmonary valve Other papillary muscles existed lower down in the right ventricle with chordae tendineae attached to the membrane A smaller independent leaflet was attached to the septum, probably representing as in Ebstein's case the septal leaflet of the tricuspid valve There was an oval opening into the conus arteriosus between the membrane and the moderator band, and small fenestra also existed in the membrane near its edge where it was attached to the chordae and papillary muscles The large auricular portion of the right ventricle was very thin-walled and contained almost no muscle tissue The foramen ovale was wide open Eustachian and Thebesian valves persisted

Geipel⁶ (1903) reported three cases of Ebstein's disease The first was that of a museum specimen of a male aged 18 years, the second was also that of a museum specimen, and the third was that of a male aged 15 years who for three months had had edema of the legs and extreme weakness This patient had some cyanosis, the heart was enlarged to left and right, there was gallop rhythm, and the heart sounds were weak and diffuse There were pulmonary

riales Just before death thrombosis occurred in the left femoral vein and the right jugular vein, and an embolus lodged in the Sylvian artery. In all three cases there was great enlargement of the right side of the heart. In the place of the normal tricuspid valve a broad band or a sack hung far down into the right ventricle, as in the cases previously described. The anterior leaflet was the best developed in all three cases, and it fused with the somewhat less well developed posterior leaflet. The septal leaflet was the most poorly developed. The orifice into the conus formed by the free edge of the anterior leaflet, the septal leaflet and the prominent moderator band was triangular or oval. In case 3 it was multilocular due to excessive development of muscular elements in conjunction with the valve. In case 1 papillary muscles were either completely lacking or were very rudimentary. Numerous chordae tendineae were present in all three cases, either in groups or discrete, they were longest on the anterior leaflet, so that that leaflet, the largest, was most free. The septal leaflet was practically devoid of chordae. The foramen ovale was patent or fenestrated in each case, but the left auricle was not enlarged in any. Geipel called attention to a case described by Riecke⁷ in 1831 which he considered to be the first recorded case of this anomaly of the tricuspid valve, but while there are certain resemblances it is certainly not the same malformation. In Riecke's case there were major defects of the right auricle, the tricuspid valve was absent, and some muscular trabeculae (but not a valve) divided the right ventricle into two cavities.

Malan's⁸ case (1908) was that of a 60 year old man who had presented manifestations of heart trouble for two years before death. The heart was moderately enlarged, and there was a loud systolic murmur. The liver was enlarged, and slight edema was noted. At the necropsy numerous splenic infarcts and thrombosis of the right iliac and the mesenteric artery were found. The left ventricle was hypertrophied and fibrotic. The right auricle and ventricle were enlarged. The tricuspid valve stretched downward toward the apex. The anterior component was large and attached partly to the annulus fibrosus and partly to the anterior wall of the ventricle. The other two leaflets were small and attached to the interventricular septum. The passage between the auricular portion of the right heart and the conus arteriosus was formed by the wall of the ventricle and the anterior leaflet. The valve was attached to the myocardium directly by means of chordae tendineae. A large Eustachian valve was present.

Heigel⁹ (1913) also reported three cases of this congenital anomaly. The first case was that of a girl of 10 years who had always been well until a week before death, when she vomited, became apathetic and complained of substernal pain and then became somnolent with a pulse rate of 56 per minute. An early systolic murmur was noted. There was a little cyanosis. Necropsy showed an early cerebral abscess with a localized purulent meningitis. The liver was congested. The right auricle and especially the right ventricle were enlarged, the latter being three times as large as the left ventricle and giving the impression of a thin-walled sac. The foramen ovale was wide open, and the Eustachian and Thebesian valves were well developed. In place of a normal tricuspid valve there was a broad connective tissue septum which was attached to part of the annulus fibrosus and to the anterior wall of the right ventricle down as far as the apex and to the interventricular septum in its lower part. This had a large anterior and a smaller posterior component with an opening between, from the edge of which short chordae tendineae passed to a small papillary muscle in the

conus arteriosus and to the moderator band. A slit-like opening into the conus was formed by the thickened free edge of the anterior component and the upper part of the interventricular septum. The lower free edge of the anterior component was attached by chordae tendineae to another small papillary muscle in the conus. A small remnant of a septal leaflet was attached to the upper part of the interventricular septum, and in the septum below this there was a large thickened plaque in the endocardium. The left auricle was not enlarged. The posterior leaflet of the mitral valve was divided by a cleft into two equal parts. There was some thickening of the free edges of the mitral valve and some of the chordae tendineae. There were two small areas of thickening of the left auricular endocardium.

Heigel's⁹ second case was a case previously studied by Verocay in 1907. The patient was a girl, aged 3 years, with cyanosis and clubbed fingers and toes, who died of measles with bronchopneumonia. She had been thought to have pulmonic stenosis. The heart was very similar to that of the first case, but papillary muscles and trabeculae were absent or very rudimentary, and the mitral valve was not abnormal. The foramen ovale was open.

Heigel's⁹ third case was that of a museum specimen of 1855 which Tietz had studied. The patient was a woman aged 38 years who died of "paralysis cordis." The right heart was quite similar to those of the two previous cases, but the anomalous tricuspid valve was thicker and roughened and was attached directly to papillary muscles without chordae tendineae. Also, the foramen ovale was closed and the auricular portion of the right ventricle was not so large. The right auricle and left ventricle were dilated, and in the left ventricle below the aortic valve and on the membranous septum there was a large thickened plaque.

Blackhall-Morison and Shaw¹⁰ (1919) reported the case of a man of 38 who had had "heart trouble" for three years and who died of pulmonary and meningeal tuberculosis. There had been marked accentuation of the first heart sound and a precordial systolic bruit. The right auricle and ventricle were both dilated and hypertrophied. The columnae carneae were decidedly hypertrophied and especially one running downward and outward from the base of the posterior cusp of the pulmonic valve. The tricuspid orifice was dilated. The septal leaflet of the tricuspid valve was "fleshy" and "sessile." The anterior leaflet was redundant and attached in its normal position. The posterior leaflet coalesced at its right boundary with the right limit of the anterior cusp but was attached abnormally low in the ventricle, and its left portion was divided into two parts. A large, tough umbrella-like flap was attached to the ventricle close to its apex, and a second smaller portion was 'fleshy' and "sessile." The foramen ovale was closed, and there was a well developed Thebesian valve. There was also congenital absence of one kidney with abnormal development of the ureter on the same side.

Blackhall-Morison¹¹ later (1922) reported the case of a man of 33 years who had been known to have heart trouble since the age of 21 years and who died suddenly. The heart was a typical specimen of Ebstein's disease. The right heart was much dilated and its wall very thin. The auriculoventricular orifice admitted the whole hand. The largest leaflet of the valve was the anterior, and the septal leaflet was small and attached vertically to the septum. There were two large papillary muscles. The membranous portion of the interventricular septum was abnormally large. The foramen ovale was closed.

Ainstein's¹² case (1927) differed from those previously described mainly in that the posterior leaflet of the tricuspid valve was the largest. The anterior leaflet was thick and suggested a triapeze. Both anterior and posterior leaflets were attached largely to the papillary muscles directly. The medial leaflet was attached directly at its free edge to the septum by short, delicate chordae tendineae. All three leaflets were joined together, the medial one not being independent as in some of the other cases described. There were two openings into the conus arteriosus, a smaller medial one and a larger lateral one. In the wall of the auricular portion of the ventricle the myocardium was practically absent. The pulmonary valves were thin but somewhat grown together, with slight stenosis. The foramen ovale was open, and the Eustachian and Thebesian valves were well developed. The patient was a woman of 20 who had had cyanosis of the lips, nose, ears and fingers since early childhood, with palpitation and dyspnea on exertion and latterly pressing pain over the sternum. Clubbing of the fingers had existed since the age of 14 years, and the patient had never menstruated. She developed symptoms and physical signs of advanced pulmonary tuberculosis, which caused death. The heart was moderately enlarged, and there was a systolic-diastolic thrill over its left side. Over the middle of the sternum a long diastolic murmur was heard, while at the apex and the tricuspid area there was a loud, long systolic murmur and a short diastolic murmur. The cervical veins were distended but not pulsating, the liver was neither enlarged nor pulsating. Toward the end edema appeared, but the cyanosis became less intense.

Finally, the case of Bassen described briefly by Abbott¹³ (1928) was that of a lad of 16 who died of erysipelas. He had had palpitation of the heart and dyspnea for several years and for two years precordial pain, some edema of the legs, and cyanosis of the lips and nailbeds. There was a very wide area of cardiac impulse with great enlargement of the heart to the left, and there were systolic and diastolic thrills at the apex, and systolic murmurs were heard over the entire precordium. At necropsy chronic passive congestion of the viscera and congenital absence of the left kidney and ureter were found. The heart was greatly enlarged, due mainly to a much dilated right auricle, and the right cardiac chambers had extremely thin walls. The tricuspid valve was absent from its usual site, but near the apex of the right ventricle there was a membranous leaflet with a stenosed multilocular orifice leading into a small ventricular cavity communicating directly with the pulmonary artery. This membrane was attached to numerous papillary muscles by "uneven" chordae tendineae. The foramen ovale was widely patent. The left ventricle was slightly dilated and hypertrophied. The mitral valve was slightly thickened along the line of closure. This was undoubtedly a case of Ebstein's disease with definite tricuspid stenosis as well as regurgitation.

CASE REPORT *

Clinical Course The patient was a white woman, aged 21 years at the time of her death. On October 4, 1930, at the age of 15 years she had first been examined at the Lymanhurst School Heart Clinic of Minneapolis, at which time she had stated that a diagnosis of heart disease had been made when she was 7 years old. There was no history of rheumatic infection. She had no complaints, and her general condition was good. She was a well developed, well nourished school girl. There was no cyanosis or clubbing of the fingers. The heart was enlarged both to the right

* Army Medical Museum Accession No. 50981

and the left. The heart sounds were slow and regular. A harsh, blowing systolic murmur was heard along the left border of the sternum, with maximum intensity in the third left interspace. This murmur replaced almost the entire heart cycle and suggested a congenital lesion, but there was no thrill. The second pulmonic sound was somewhat accentuated. Roentgenographic examination revealed marked cardiac enlargement, and a lateral film made with the esophagus filled with barium showed definite posterior displacement of the esophagus. The transverse thoracic diameter was 24.0 cm, and the total transverse diameter of the heart was 15.0 cm, with M L measuring 9.2 cm and M R, 5.8 cm.

The patient was not seen again until January 11, 1933. She still had no complaints and looked very well. The heart was essentially the same except for the presence of frequent premature contractions. The vital capacity was 1500 cc.

FIG 1 Enlarged heart, especially toward the right

Roentgen-ray examination revealed the same marked cardiac enlargement, with the measurements all slightly greater than before.

When examined again on March 31, 1934 she was well except for some dyspnea. The hands were now cold, clammy and cyanotic, and there was a suggestion of clubbing of the fingers. The vital capacity was 1420 cc.

On March 13, 1935 the findings were essentially the same, but cyanosis and clubbing of the fingers were not definite. There were numerous premature beats. The long, harsh murmur was best heard in the fourth interspace just to the left of the sternum and seemed to occupy the entire heart cycle. It was fairly well transmitted toward the apex but was not heard beyond the precordium nor in the neck. The second pulmonic sound was not audible. The blood pressure was 104 systolic and 90 diastolic. The roentgenogram showed the heart to be considerably enlarged to both sides (figure 1). There was no enlargement in the region of the superior or

median convexities, and although the enlargement in the region of the right auricle was most marked and unusual the contour of the heart could not be said to be typical of any lesion. The transverse thoracic diameter was 25.3 cm, the total transverse diameter of the heart was 15.8 cm, with M-L measuring 9.6 cm and M-R, 6.2 cm. The vital capacity was only 1000 cc. The electrocardiogram showed left axis deviation, rate 72, PR interval 0.16 sec, occasional ventricular premature beats, QRS 0.16 sec in Leads I and II, and 0.12 sec in Lead III, P-wave positive in all leads, T-waves in Lead I variable and either positive or negative (figure 2). The second lead was most interesting in that it showed changes in the shape of the main ventricular complexes, suggesting that the excitation wave was taking different directions at different times.

FIG 2 Conventional three leads left axis deviation, prolonged QRS complexes, variation in form of ventricular complexes, Lead II

The patient attended a dance on the night of June 29, 1936 and was apparently in her usual good health when she retired at 10 p.m. Her parents were awakened by a noise in her room at about 2 a.m. the same night and upon investigation found her to be dead in bed.

Necropsy Necropsy was performed at 9:30 a.m., June 30, 1936, by Dr. J. S. McCartney of the University of Minnesota School of Medicine. There was no cyanosis or edema. Except for the heart there was little to be found besides intense acute congestion of the spleen which weighed 275 gm, of the liver which weighed 1525 gm, and of the kidneys which were not enlarged. The lungs presented no evidence of congestion or edema.

Gross Description of the Heart The pericardial sac measured 15 cm in its transverse diameter. The heart appeared to be enormous. When emptied of blood it weighed, however, only 275 gm. Even upon superficial inspection it was evident

that the great size of the organ was due to tremendous dilatation of its right chambers. Externally the right ventricle appeared to be moderately enlarged, but what seemed to be the right auricle was a very dilated, thin-walled chamber which obviously encroached upon the right ventricle. Its inferior and posterior walls were especially thin. The venae cavae were in their normal positions with respect to the right auricle, which formed the right one-third of the anterior surface of the heart, the pad of fat about 3.5 cm in diameter and about 1.0 cm in its thickest part. The left ventricle and auricle were both relatively small, and the former occupied very little of the anterior surface of the heart and practically none of the apical portion. The mouths of the pulmonary veins were not present in the specimen after removal from the body, but it was certain that they occupied their usual position. The aorta and pulmonary artery were joined with their proper ventricle and were in normal relation to each other. The auricular appendages were in their normal positions.

After opening the heart in the usual manner it was seen that both the right auricle and ventricle, especially the former, were greatly dilated and that the tricuspid valve was displaced and malformed. The left auricle and ventricle were comparatively small but appeared normal. The two coronary arteries, which were pliable and smooth-walled, had their usual origin. The circumflex branch of the right passed obliquely downward and toward the right on the anterior surface of the heart and then toward the left to the very inferior edge of the heart, forming a semicircle. This apparently anomalous location was due to the great enlargement of the right auricle, which formed the right one-third of the anterior surface of the heart, the vessel was actually in its normal location in relation to the right auricle and ventricle. The left coronary artery divided as usual into the anterior interventricular artery and the left circumflex artery. The latter ended in two large branches, one on the lateral wall of the left ventricle which ran obliquely anteriorly and downward from the posterior junction of the auricles and the ventricles, and another which ran downward from this point toward the lower edge of the heart on the posterior wall of the right ventricle and apparently represented the posterior interventricular artery, although it did not lie in the posterior interventricular sulcus.

The aortic valve appeared normal and measured approximately 5.0 cm in circumference. The membranous portion of the interventricular septum was quite small, the muscular portion reaching almost up to the base of the aortic valve. The mitral valve had its normal structure and its normal chordae tendineae and papillary muscles. The mitral orifice was about 9.0 cm in circumference. The thickness of the left ventricle near its base was 1.0 cm. The depth of this ventricle was 7.0 cm. The endocardium of the left auricle and ventricle appeared normal, as did their musculature.

The right side of the heart presented a very anomalous appearance and was a typical example of Ebstein's disease (figures 3 and 4). By far its greater part functioned as the auricle, since the tricuspid valve was displaced down into the ventricle, its line of attachment passing around the wall of the ventricle in a vertical direction instead of transversely between the auricle and the ventricle, dividing the ventricle into a proximal auricular two-thirds and a distal one-third which functioned as a ventricle. However, the true auricle and ventricle were joined as normally at the annulus fibrosus, which ran transversely, and the true auriculoventricular orifice was wide open and actually dilated. There was a very definite Eustachian valve in its normal location, and the coronary sinus was in its normal situation below this, although it did not have a Thebesian valve. The fossa ovalis was at its normal site but was patent, there was a thick fold in the left auricle across the foramen ovale, which was open at the top. This fold apparently made closure of the foramen fairly competent except for a small fenestrum in the lower part of the fold. The pectinate muscles of the right auricle were normal and had their origin at the annulus fibrosus.

The auricle bulged far out and its wall was translucent and composed almost entirely of connective tissue. The central fibrous body was in its normal position.

The anterior papillary muscle of the right ventricle was displaced from its usual site downward and forward toward the very apex and lay in the functional right ventricle beneath the displaced tricuspid valve. The tricuspid valve formed a

continuous fold around the interior of the right ventricle and could be divided only arbitrarily into three leaflets. The septal or medial leaflet was attached vertically to the upper half of the interventricular septum below and anterior to the central fibrous body. It had short broad chordae tendineae passing forward into the prominent moderator band. This leaflet passed downward to fuse without a definite line

of demarcation into the much dislocated posterior leaflet, the free edge of which was rounded and thickened but not apparently diseased. It was about 1.5 cm wide, and its attachment was vertically downward along the middle of the interventricular septum toward the apex. On its septal surface it was attached to a small teat-like papillary muscle, and at its lower extremity it was attached directly on its under surface to the papillary muscle in the apical region of the ventricle already referred to. Near the apex it fused with the larger anterior leaflet. The latter was attached at its upper limit to the annulus fibrosus and anterior upper limit of the interventricular septum, being fused with the medial leaflet where one stout chorda tendinea also attached it to the upper portion of the moderator band. Its line of attachment

FIG 4 Anterior view of right auricle and ventricle held open at anterior incision, looking into functional right ventricle, RV², and conus arteriosus to right of moderator band, MB. then passed down the anterior wall of the ventricle toward the apex where it fused with the posterior leaflet. It was roughly triangular and about 2.5 cm wide in its widest portion. Its free edge was rounded and thickened like that of the posterior leaflet. It had a few delicate chordae tendineae attached to the under surface of its apical portion which fixed it lightly to the apical part of the ventricle, but its main attachment there was directly to the papillary muscle. The line of attachment of the whole valve measured about 1.20 cm.

The moderator band ran obliquely downward and forward from below the central fibrous body between the conus arteriosus and the small part of the right ventricle below and anterior to the displaced tricuspid valve. It formed a muscle

septum dividing the conus arteriosus from the functional right ventricle and was attached to the anterior part of the interventricular septum and the anterior wall of the conus. In its upper portion it was merely a trabeculum protruding from the interventricular septum, but in its lower half it was very broad, fan-shaped and thinner, and projected far out into the ventricular cavity and the conus.

The apical region of the ventricle beneath the tricuspid valve was a small chamber divided into two parts by the papillary muscle and a small muscular trabeculum joined to it. These spaces communicated with the small portion of ventricle between the valve and the broad moderator band by means of a cleft.

Histologic Study of the Heart Two large blocks of tissue were excised from the heart which included most of the auriculoventricular septum and all of the interventricular septum. These blocks were imbedded in paraffin, and serial sections of 10 microns thickness were cut horizontally from above downward. All sections were mounted, and every fifth section down to section 670 of block 1 and every tenth section beyond that was stained with Masson's trichrome stain. There were 2820 sections made from block 1 and 1680 from block 2, making a total of 4500 sections. The auriculoventricular node and bundle were quite normal in structure and in their relationship to the true right auricle and the central fibrous body (figure 5). The division of the bundle of His into its two branches began at about section 490. On the right side of the interventricular septum the tricuspid valve was seen to be attached to the right of the middle in a vertical direction from above downward. The moderator band became more and more prominent as the sections descended, until in the lower part of block 1 it formed a high, moderately thin projecting muscular band at the anterior edge of the septum. The right bundle branch, normal in structure throughout its course, ran at first directly beneath the line of attachment of the septal leaflet of the tricuspid valve in a rather prominent small projection, surrounded on its peripheral and lateral sides by a fibrous rim and deeply by the septal musculature (figure 6). It changed in shape in its transverse section as it descended, becoming first fusiform, then roughly triangular and then oval. It gradually moved anteriorly from the middle of the septum, leaving the projection mentioned at about section 800 and moving toward the base of the moderator band which it reached at section 1060. It was subendocardial in this migration. The right bundle branch then gradually ascended along the posterior edge of the moderator band, lying beneath the anterior attachment of the septal leaflet as it ascended. The branch then gradually passed up to the unprotected summit of the moderator band which it reached at about section 2500, becoming a little deeper with a small rim of myocardium between it and the endocardium (figure 7). Below the middle of the interventricular septum in block 2 the moderator band became divided gradually from summit to base by a cleft, and the right bundle branch gave components to the two parts, spreading out broadly beneath the endocardium along the adjacent sides of the cleft and finally in the upper third of the block losing its identity (figure 8). The trabeculae carrying the bundle branch were at the base of the fan-like expansion of the moderator band.

The left bundle branch appeared quite normal in structure and location throughout its course beneath the endocardium covering the left side of the interventricular septum (figures 5, 6, 7 and 8). It gradually spread out to become broader and broader. About the middle of the septum it became definitely thicker in parts and began to divide into anterior and posterior divisions, which passed down toward the base of the anterior and posterior papillary muscles respectively and finally lost their identity in the lower part of the septum.

The endocardium and myocardium presented no evidence of ancient or recent inflammation, except for a small mass of fibrous tissue in the myocardium at about the middle of the septum and near its right ventricular surface, and changes in the wall of a moderately large intraseptal artery in the same general locality. These changes were suggestive of, but not pathognomonic of ancient rheumatic arthritis. Practically all other arteries appeared quite normal.

DISCUSSION OF CASE

The case was a typical example of Ebstein's disease. Congenital heart disease was diagnosed, but the type of malformation could not be determined before death. The electrocardiographic abnormalities suggested left bundle-branch block (new terminology), and it had been hoped that the histologic study would show definite evidence that would aid in settling the controversy now waging concerning the terminology of intraventricular block. However, the left bundle branch was entirely normal, and although the course of the right bundle branch was somewhat abnormal it conformed in a general way to that of the normal heart, and the branch was not interrupted at any part of its microscopically recognizable portion. One must conclude, therefore, that the electrocardiogram can not definitely be designated as that of bundle-branch block but rather of left axis deviation due perhaps to an electrical imbalance between the right and left ventricles associated with prolongation of intraventricular conduction time.

Of the cases described in the literature this case seemed to resemble most closely that of Arnstein. The components of the three leaflets were fused and continuous, and it was impossible to say exactly what their limits were. The valve was obviously incompetent, and tricuspid regurgitation must have occurred. However, the extracardiac signs of this dysfunction were lacking because of hemodynamic properties which will be discussed later.

COMPARISON OF CASES

The 16 cases of Ebstein's disease were similar in their fundamental nature, namely, the displacement of the valve downward into the right ventricle. In all, the anterior leaflet was partly attached to the annulus fibrosus, whereas the posterior leaflet had usually very little connection with it, and the medial or septal leaflet was attached to it in some cases and not in others. In almost all of the cases the anterior leaflet was much larger than the other leaflets. In some cases the septal leaflet appeared as an isolated, almost functionless flap attached to the interventricular septum, and in others it was an integral part of the whole valve. In some, the valve resembled a flapping sail, whereas in others, as in our case, it did not give that impression because the leaflets, especially the anterior, were either not so large or were more closely held by chordae tendineae and papillary muscles to the ventricular wall. There was considerable variation in the number, size and position of the papillary muscles and chordae tendineae. In some there were both present, in others there were mainly only papillary muscles or only chordae. The so-called moderator band, which in the human heart is usually poorly developed, was frequently much enlarged.

The amount of the ventricular cavity proximal and distal to the valve varied, but the distal portion was usually much smaller than the proximal, a condition which was exaggerated by the usually great dilatation of the so-called auricular portion of the ventricle. The degree of dilatation proximal to the valve, as well as the thinness of the wall, was apparently determined by the amount of regurgitating blood and possibly by the length of life. In all of the cases the true auriculoventricular ostium was enlarged, but there was considerable variation in the position, form and size of the actual valvular orifice between the auricular portion of the ventricle and the remainder of the ventricle, which consisted

mainly of the conus arteriosus. In all of the cases it appeared probable that the valve was incompetent to close its orifice completely, thus allowing regurgitation. In one case, at least, there was also definite stenosis of the orifice. There was considerable variation in regard to accessory fenestria of the leaflets. The pulmonary conus varied moderately in size and in the thickness of its wall, and there were also variations of a relatively minor nature in the pulmonic valve.

Associated cardiac anomalies were of minor nature. The most common and most important was the patency of the foramen ovale, but this was not present in all cases. It was undoubtedly secondary to the increased pressure in the right auricle. The amount of blood flowing through it into the left auricle was not sufficient in most cases to cause appreciable enlargement of that chamber, since there was probably a diminished amount of blood flowing into the left auricle from the pulmonary circulation. There was considerable variation in the Eustachian and Thebesian valves, and when well developed they were probably of some importance in preventing the back flow of blood into the venae cavae and the coronary sinus.

The split posterior mitral leaflet in one case was of interest, but only as an associated anomaly.

The thickened endocardial plaques and the thickenings of valve leaflets and chordae tendineae in a few of the cases were probably only incidental.

EXPLANATION OF THE ANOMALY

Opinions have varied as to the cause of the anomaly. A few authors have attached great importance to intra-uterine endocarditis, but this, when it occurs, is probably only incidental and due to the predisposition of such malformed parts to inflammation. The most plausible explanation seems to be that of MacCallum,⁴ who states: "The valves are, of course, formed on the medial side by a prolongation of the septum intermedium, on the lateral side by an involution of the wall of the auricular canal. If in an early stage these endothelial cushions reach a greater extent than normal and retain their attachment to the muscular trabeculae, they would in time become a membrane, supported by muscular trabeculae. This might occur only on the lateral side, the valves produced from the septum developing in part normally. The free edge has possibly lost its muscular attachment as a result of the inefficiency of muscular action in the direction in which the blood stream affects it."

The malformation occurs only in the otherwise essentially completely developed heart and probably before the eighth week of fetal life. According to Mall the posterior leaflet develops independently from the posterior wall of the endothelial tube, while the others originate from the endothelial cushions. In Ebstein's disease the posterior leaflet is the most anomalous, while the medial leaflet, though deformed, has always the most normal parts. Heigel believes that the usual large size of the anterior leaflet may be due to a compensatory effort.

CLINICAL FEATURES

It would appear to be impossible to make the diagnosis of Ebstein's disease during life. The type of enlargement of the heart is not characteristic. There

may be both systolic and diastolic murmurs, with or without a thrill, but more often there is only a long, loud systolic murmur of greatest intensity in the third and fourth intercostal spaces close to the left border of the sternum. The pulmonic second sound is usually not accentuated.

Cyanosis and clubbing of the fingers may or may not be present. The presence of cyanosis depends, of course, upon the amount of venous blood flowing into the left auricle through the foramen ovale and the degree of diminution of the flow of blood into the pulmonary artery. The amount of cyanosis in one case decreased near the end of life, probably because the failing right ventricle ejected less venous blood through the foramen ovale.

The signs usually associated with tricuspid insufficiency, such as positive venous pulsation in the neck and pulsating liver, occur usually only when heart failure is precipitated by some serious infection, probably mainly because of the great enlargement of the right auricular portion of the heart, which acts as a reservoir, and partly in most cases because of the patency of the foramen ovale. The musculature of the auricular portion of the right ventricle is frequently practically absent, so that this portion of the ventricle plays little part in propelling blood up toward the true auricle.

The condition is compatible with long life, and death from heart failure alone is not the rule. Three patients died unexpectedly. The occurrence of pulmonary tuberculosis in four of the cases is interesting, showing perhaps an increased susceptibility of the lungs because of their reduced blood supply, as in cases of pulmonary stenosis.

Retarded development in the early years of life was noted in several cases, but usually after puberty growth was speeded up. In one case menstruation did not occur, and the uterus was found to be hypoplastic.

OTHER EXAMPLES OF CONGENITAL TRICUSPID INSUFFICIENCY

Ebstein's disease is not the only cause of congenital tricuspid insufficiency. As other interesting examples we should like to refer to the cases of Hotz and of Ariel. Hotz¹⁴ reported two very similar cases, one a girl who died at the age of 13 years, the other a boy who died at 12. In both cases there was cyanosis. In both the heart was enlarged, with accentuation of the pulmonic second sound, and roentgenograms showed marked enlargement in the region of the pulmonary conus. In one there was a variable soft systolic murmur, in the other there was no murmur, but toward the end paralysis of the left recurrent laryngeal nerve and diminution of the left radial pulse developed due to pressure upon the nerve and the aortic arch by the greatly enlarged pulmonary artery and right auricle. Death was due to heart failure with tricuspid insufficiency in both cases. Necropsy revealed that the tricuspid valve had only two short leaflets in one and one well developed and two rudimentary leaflets in the other.

In Ariel's¹⁵ case a cyanotic male infant died after two days. There were lobar pneumonia and passive congestion of all of the organs. Both the mitral and tricuspid valves were represented by tumor-like processes which were interpreted as congenital overgrowths or hyperplasia of the embryonic connective tissue of the endocardial cushions. Microscopic sections showed these anomalous valves to consist of avascular, thick collagen fibers.

SUMMARY

Ebstein's disease of the heart is a rare congenital malformation consisting essentially of downward displacement of the tricuspid valve in an otherwise completely developed heart. The right auricle is greatly enlarged, and the foramen ovale is usually patent. The true right auriculoventricular ostium is enlarged. The tricuspid valve is obviously incompetent, but venous congestion and pulsation do not occur unless an additional strain or damage precipitates heart failure. The condition is not incompatible with long life. Pulmonary tuberculosis is a common complication, probably because of reduced pulmonary blood flow. The lesion may be suspected with other possibilities but can not be positively diagnosed during life.

The sixteenth case is reported. The patient was a woman aged 21 years who was known to have a congenital heart lesion and who died unexpectedly. Necropsy revealed only the heart lesion and acute congestion of the viscera. The electrocardiogram had revealed left axis deviation and prolonged intra-ventricular conduction time. Histologic study of the conduction system by means of 4500 serial sections did not reveal any significant lesion, although the course of the right bundle branch was somewhat anomalous.

EDITORIAL

THE INCIDENCE OF TRICHINOSIS

Hall and Collins^{1, 2, 3} have recently reported a study of 300 human diaphragms from autopsy cases in 10 hospitals in Washington, D C , and from one hospital in Baltimore which showed that trichinae were present in 13.67 per cent. This figure seems surprisingly high but as Hall points out this is only because we look upon human trichinosis as a rare disease. Previous investigators in different parts of the country have all agreed that latent trichinosis as evidenced by infestation of the diaphragm with trichinae is to be found in a significant percentage of the population. A tabulation of earlier investigations shows percentage incidences found in different sections of the country ranging from 3.5 per cent in New Orleans to 27.6 per cent in Boston. In general the highest incidences were found on the east and west coasts and the lowest in the far south.

This geographic variation the authors are inclined to attribute chiefly to garbage and swill feeding of pigs near the large eastern and western population centers whereas in the south it is more usual for swine to run free in the woods and forage for themselves. In swill and garbage pork scraps are found and such scraps containing trichinae perpetuate the disease in swine. The eating by hogs of trichinae infested rats is a less frequent cause. Both Hall and Schwartz in separate studies showed that live trichinae are far more frequently found in garbage-fed than in grain-fed hogs. The incidence in garbage-fed hogs was 4.8 to 5 per cent and in grain-fed hogs 1 to 1.5 per cent. It is of interest to note that trichinae are to be found far more frequently in the human than in the porcine inhabitants of the United States.

The above data as to geographic variations of incidence in man are not to be accepted as conclusive. The number of cases studied and the methods employed in their study have been too variable to warrant entire confidence in any statistical interpretations. Hall and his coworkers believe, however, that few errors are made in the interpretation of the finding of encysted living or dead trichinae since these are easily recognized, but they feel that unless two or more methods are used many positive cases will be overlooked. In their studies they made a direct microscopic examination of one gram of diaphragm muscle pressed flat between heavy glass plates. In addition varying amounts, averaging 113 grams, of diaphragm were digested in artificial gastric juice for approximately 24 hours and the re-

¹ HALL, M. C., and COLLINS, B. J. Studies on trichinosis. I. The incidence of trichinosis as indicated by postmortem examination of 300 diaphragms, Public Health Reports, 1937, *lii*, 468-490.

sultant mixture poured on the screen of a Baermann apparatus. The water coming through as well as the material on the screen were examined for trichinae. The microscopic press-preparation was found most valuable for detecting encysted dead larvae while live larvae were more readily discovered by the digestion-Baermann method. The authors believe that only through semi-quantitative methods applied to very large series of cases in different localities can we obtain a more accurate picture of the prevalence of this potentially serious condition.

In the various reports on the incidence of trichinosis in the United States as determined by postmortem studies of the diaphragmatic muscle Hall found 222 positive cases reported. He was unable to find evidence that a diagnosis of trichinosis had been made in life in a single one of these 222 cases. One reason for this lack of recognition of the infestation may be that in a majority of the cases the number of larvae which entered the circulation and eventually became encysted in the muscles was too small to have caused definite clinical symptoms. It is not known of course whether the number of larvae per gram of diaphragmatic muscle is a dependable index of the concentration of larvae in other portions of the body. We do know that the diaphragm is uniformly attacked and usually contains a high concentration of trichinae. Hall's and Collins' careful work gives the number of trichinae per gram in each of their 41 positive cases. This number is found in their tabulation to vary between 0.006 and 993. In only two cases were there more than 100 trichinae per gram and in only 11 cases were there more than 10 per gram. In 14 cases the average number was less than 1 per gram. No information is yet available to indicate what degree of infestation is necessary to produce the clinical picture of trichinosis but it is probable, Hall and Collins feel, that cases with less than 1 trichina per gram of muscle present few symptoms, and that those with over 100 trichinae per gram show a clear cut clinical picture of trichinosis. Between these extremes there must occur many cases with mild or atypical symptoms which we do not at present associate with clinical trichinosis. There is here undoubtedly an unexplored clinical field. In addition to the symptoms now usually considered as cardinal—gastrointestinal disturbances, fever, sub-orbital edema, painful muscles, pneumonia—we must learn to suspect of trichinosis infestation cases showing certain ocular lesions, atypical myocardial involvement, meningismus, encephalitis with stupor, diaphragmatic pleurisy, urticaria, etc. The search for eosinophilia, the biopsy of muscle, the search for trichina larvae in the blood and cerebrospinal fluid, the skin test and the precipitin test should be applied more freely in our clinical investigations of obscure disease processes.

REVIEWS

The Practitioner's Library of Medicine and Surgery Supervising Editor, GEORGE BLUMER, M A (Yale), M D, F A C P, David P Smith Clinical Professor of Medicine, Yale University School of Medicine, Consulting Physician to the New Haven Hospital *Volume XII Preventive Medicine and Hygiene* Associate Editor IRA V HISCOCK, M A, C P H, Professor of Public Health, Yale University School of Medicine xxxviii + 993 pages, 45 illustrations D Appleton-Century Company, Inc, New York 1937 Price, \$10 a volume

The previous eleven volumes of *The Practitioner's Library* have been reviewed in the ANNALS as they have appeared. The twelfth volume, *Preventive Medicine and Hygiene*, is an interesting and valuable addition to the set. Twenty-five authors, each chosen for special knowledge of some particular field, have contributed the forty-two chapters. The associate editor, Ira V Hiscock, has himself provided nine chapters. The subject matter is grouped into four parts of which Part I deals with Individual Hygiene. Of special interest to the general practitioner are the chapters in this section on General Considerations Concerning the Periodic Health Examination by Haven Emerson and on The Content and Technics of Periodic Health Examinations by Harold S Diehl. The benefits of an annual or semi-annual health audit so overwhelmingly outweigh the arguments against this procedure that the practitioner must be prepared to meet an increasing demand for this form of service. Unless the periodic examination is conducted in a thoroughly scientific manner and its results properly recorded by some such method as described in these chapters, its value may be lost and the procedure fall into disrepute. The practitioner will find these chapters full of practical suggestions applicable to his routine examinations of sick people as well as of those who are presumptively in a state of health. The chapter on Sex Hygiene by M J Eaner and W F Snow is especially valuable. In it the practitioner will find safe and reasoned answers for the many questions which are asked him about juvenile sexuality, masturbation, continence and sex-adjustment in marriage. Part II is devoted to Group Hygiene and will prove of special use to the physician who is the health advisor to a rural community. The hygiene of the home and of educational institutions and the health hazards of farming are topics which are fully developed. Part III deals with Community Health and here will be found basic information on the protection of food and water supplies and on sewage disposal. In the smaller communities the physician is frequently called upon to advise or even direct in such matters. Likewise the control of communicable diseases in general, and of tuberculosis and the venereal diseases in particular, is discussed here. Part IV covers The Prevention of Specific Diseases. The chapter on Prevention of the Infectious Diseases is by William H Park and Morris Seigel, those concerned with Toxic and Physical Agents by Emery R Hayhurst. It is impossible, in a limited review, to refer specifically to each of the chapters treating of prevention of disease in various anatomical systems. As the reviewer has had occasion to write in regard to preceding volumes, this series is remarkably free from typographical errors for a first edition. There is an unavoidable variance in literary style and an occasional lapse into medical slang which is out of harmony with the dignity of the work as a whole. Should we be alarmed or relieved that (p 853) "The mortality in the best clinics is from 2 to 8 per cent of all prostates who enter," or that (p 855) "The future of the testicular tumors is always in doubt"? The nice press work and adequate indexing which have been found in previous volumes are maintained here. This twelfth volume is a worthy addition to the *Library*, and fully qualified to stand alone as an adequate textbook of Preventive Medicine and Hygiene.

C V W

Orthodiascopy By CHESTER M KURIZ, M D, F A C P, Assistant Professor of Medicine, University of Wisconsin, Cardiologist to the State of Wisconsin General Hospital 247 pages, 15 × 22 cm, indexed The Macmillan Company, New York 1937 Price, \$3 50

The author describes the technic of recording orthodiagrams and the apparatus necessary The normal cardiac silhouette is depicted and in subsequent chapters alterations from normal in size and silhouette due to the various diseases of the heart are discussed The author's observations indicate that the method of determining the frontal area of the heart described by Hodges and Eyster gives the most reliable evidence of cardiac enlargement and nomograms for determining the expected (normal) frontal area are presented The author holds that the combination of fluoroscopy and orthodiascopy is the most valuable roentgenologic method of examining the heart and recording its size and contour With this point of view the reviewer is in entire accord However, no roentgenologic method as yet devised gives infallible evidence as to whether lesser deviations from an expected normal mean cardiac enlargement Such decisions ultimately must be based not on measurements alone but on other considerations as well It is only fair to state that the author recognizes this fact in spite of his enthusiasm for the methods described It would have been wise to have stressed it more For many reasons it would seem obvious that the cardiologist is the logical person to perform such examinations This book is recommended to those interested in this subject

W S L, JR

Biological Time By P LECOMTE DU NOUY, Chief of the Division of Molecular Physics, Pasteur Institute, Paris, formerly Associate Member of the Rockefeller Institute Foreword by Alex Carrell, M D ix + 180 pages, 20 × 12 5 cm Macmillan Co New York 1937 Price, \$2 00

This interesting volume is divided into three main headings The first, entitled "The Biological Problem and Methods," compares the methods of the physical scientist with those of the biologist and in it the limitations of physical methods in biology are emphasized

The second division of the book is entitled, "Cicatrization of Wounds and Tissue-Culture" In this a comprehensive survey of the cicatrization of wounds on individuals of various age groups is reported Many of the observations of the author were made on soldiers during the World War The rapidity of healing in the young and the delayed cicatrization in late life are clearly demonstrated Many diagrams are included illustrating these phenomena Further work in this section is reported on the speed of cicatrization with respect to the area of the wound Several curves expressing this relationship in various wounds are given and a general exponential equation giving mathematical expression to the subject has been developed

Part three is entitled, "Time" Much space is given to a consideration of the idiology of time as one of the spacial dimensions Man's concept of time was plotted against his age and interestingly enough the hyperbolic curves obtained by the plotting of man's concept of the time against age and wound cicatrization against age coincide Finally the author questions whether quantitative symbols will ever express life or psychological phenomena in general—for mathematics cannot express the beauty life so often embodies

This book should capture the imagination of the scientifically minded physician

J C K, JR

The Postmortem Examination By SIDNEY FARBER, M D, Associate in Pathology, Harvard Medical School 201 pages, 16 X 23.5 cm Charles C Thomas, Springfield, Ill 1937 Price, \$3.50

Beginning with a brief historical introduction which sketches the influence of the necropsy upon clinical medicine, this manual proceeds with a detailed consideration of the methods employed in the systematic postmortem examination. The clinical methods of Virchow and Rokitsky are used as the basis of the discussion with alternative procedures mentioned when indicated. The exposition is detailed and clear. Helpful illustrations are included from time to time. A brief reference to the problems presented by the medico-legal postmortem is given, but the reader is referred to other sources for more complete information. Because of the author's experience, the section devoted to necropsies on infants and children is of especial interest. Included also are helpful tables of average weights of organs in both adults and children. An adequate index is presented. The book can be heartily recommended as a useful guide for the neophyte and one which points the way toward a high standard of excellence in the performance of the postmortem examination.

M S S

William Withering The Introduction of Digitalis into Medical Practice By LOUIS H RODDIS, M D, Commander, Medical Corps, U S N 131 pages, 14 X 19.5 cm Paul B Hoeber, Inc New York 1936 Price, \$1.50

The reviewer has not previously read a biography of William Withering, and indeed no other seems to be extant. The author's source material is revealed in the appendix and includes the memoir by Withering's son. One does not gain a very adequate impression of the personality of the man from this biography, but this is doubtless due to the lack of material from which to draw such a picture rather than to any fault of the author. We do see Withering to be a man interested in many scientific pursuits as so many were in his time. We find him to be a botanist of note, a mineralogist, a student of climatological phenomena and an observing clinician. He was interested in the social movements of his day and was a sympathizer with the French Revolution. His medical fame has a secure base in his observations on digitalis. This drug was first brought to his attention in 1775 as a "family recipe for the cure of dropsy." With his botanical knowledge it was not difficult for him to discover that the foxglove was the active ingredient. The author quotes frequently from Withering's writings and includes in the text the section of the book on digitalis dealing with Preparation of the Drug, Effects, Rules and Cautions, Constitution of the Patients, Inferences. Although Withering attributed the therapeutic qualities of foxglove to a diuretic action, but little has since been added to his clinical observations.

W S L, Jr

Weight Reduction, Diet, and Dishes By E E CLAXTON, M B, B S (London), D T M and H 199 pages, 14 X 22 cm William Heinemann (Medical Books) Ltd, 99 Great Russell St, London, W C I 1937 Price, 8s 6d net

This is a readable and useful book on the treatment of overweight, couched in language midway between vernacular and textbook. Endowed with British whimsy, and aimed for the use of the lay person, it proceeds with moderate pedagogical repetition at a slow and steady pace. There is an unusual plowing up of superstitions and a most serious discussion of the disadvantages of being fat. The "banana and milk" diet is properly expounded. An undue emphasis is put on salt and on the ductless glands which are dragged in as a sort of *deus ex machina* whenever the discussion seems to be getting out of hand. The recipes are abundant and explicit. They are unusual in that they make individual servings. It will be a useful handbook for cooperative patients, and an acceptable textbook for dieticians and students.

C A

COLLEGE NEWS NOTES

New Life Member Dr Louise Tayler-Jones (Fellow), McLean, Va., became a Life Member of the American College of Physicians on November 11, 1937

GIFTS TO THE COLLEGE LIBRARY

Receipt is gratefully acknowledged of the following donations to the College Library of publications by members

Books

- Rear Admiral C S Butler (MC), U S N (Fellow), Washington, D C—an autographed copy, "Syphilis Sive Morbus Humanus",
Dr William Fitch Cheney (Fellow), San Francisco, Calif—"The Diagnosis and Treatment of Diseases of the Stomach and Intestines",
Dr J C Geiger (Fellow), San Francisco, Calif—"Bacteriology of Specific Communicable Diseases Handbook of Public Health Bacteriology",
Dr Frank H Krusen (Associate), Rochester, Minn—an autographed copy, "Physical Therapy in Arthritis",
Dr Aaron E Parsonnet (Fellow), Newark, N J, and Dr Albert S Hyman (Fellow), New York, N Y—"Applied Electrocardiography",
Dr Bernard L Wyatt (Fellow), Tucson, Ariz—an autographed copy, "Chronic Arthritis and Fibrositis"

Reprints

- Dr Marcos Fernan-Nunez (Associate), Milwaukee, Wis—"Medicine as a Career",
Dr Fred M F Meixner (Fellow), Peoria, Ill—"Treatment of Pneumonia",
Dr Lewis J Moorman (Fellow), Oklahoma City, Okla—"Francis Adams of Banchory", "Medicine Versus State Medicine", "Multiple Calcifications in the Spleen", "The Home Versus the Preventorium in the Management of Tuberculosis Contacts", "The Tuberculosis Problem"

Acknowledgment is also made of the receipt of a report prepared by the Bureau of Medical Economics of the American Medical Association, entitled "Group Hospitalization"

Dr Currier McEwen (Fellow), New York, N Y, has been appointed Dean of the New York University College of Medicine Dr McEwen is thirty-five years of age, the youngest medical college dean in the United States He graduated from New York University College of Medicine in 1926, and heretofore has been Assistant Professor of Medicine and Assistant Dean and Secretary of his Alma Mater

Dr David I Abramson (Associate), formerly of Brooklyn, N Y, has been appointed Director of Cardiovascular Research in the Institute for Medical Research of the Jewish Hospital, Cincinnati, Ohio, as of November 1, 1937

Dr S A Slater (Fellow), head of the Southwestern Minnesota sanatorium at Worthington, was elected president of the Minnesota Public Health association at the

annual meeting of that organization in St Paul He will assume office January 1, 1938

Dr August A Weiner (Fellow), St Louis, Mo, gave two lectures under the auspices of the Iowa State Medical Society for their postgraduate course at Sheldon, Iowa, on November 1, and at Waterloo, Iowa, on November 2, his subject being "Gonad Hormones in Health and Disease"

The Tenth Annual Graduate Fortnight of the New York Academy of Medicine was held from November 1 to 12, 1937, and was devoted to "Medical and Surgical Disorders of the Urinary Tract" Dr James Alex Miller (Fellow and ex-President), is President of the Academy On the Graduate Fortnight Committee appeared the names of the following Fellows of the College Dr Bernard Sutro Oppenheimer, Chairman, Dr Ralph Henderson Boots, Dr Thomas T Mackie, and Dr Herman O Mosenthal

Among presentations on the program were Dr James Alex Miller (Fellow), Address of Welcome, Dr George Baehr (Fellow), "The Pathology of Nephritis", Dr Robert F Loeb (Fellow), "Clinical Aspects of Nephritis", Dr Herman O Mosenthal (Fellow), "Clinical Aspects of Hypertension, Including Malignant Hypertension", Dr W W Herrick (Fellow), "Vascular and Renal Complications of Pregnancy"

The program of afternoon hospital clinics included presentations by the following Fellows Dr Soma Weiss (Boston), Dr I W Held, Dr William Goldring, Dr Walter W Palmer, Dr Robert F Loeb, Dr George A Sheehan, Dr B P Stivelman, Dr B S Oppenheimer, Dr A M Master, Dr Herman O Mosenthal, Dr Benjamin I Ashe, Dr Lewis A Conner, Dr C E de la Chapelle, Dr W W Herrick, Dr S Edward King, Dr Albert S Hyman, Dr Maximilian A Ramirez, Dr James R Lisa and Dr I Seth Hirsch

At the annual meeting of the California Section of the American Sanatorium Association, held at Orange, California, November 12, 1937, the following Fellows participated, Dr E W Hayes (Fellow), acting as one of the hosts Dr H G Trimble, presentation of report on resolutions to the American Sanatorium Association and the National Tuberculosis Association, Dr Chesley Bush, resume of the present status of the Association of Thoracic Surgeons, Dr F M Pottenger, follow-up program of cases discharged with a favorable result from the Tuberculosis Sanatorium, Dr Chesley Bush (with Dr Everett Morris), choosing a site for the new Tuberculosis Sanatorium, urban vs rural locations, a division of the General Hospital or individual entity, Dr Harold G Trimble (with Dr W A Hodges), the present place and future development of the Preventorium

Dr Edward J Engberg (Fellow), St Paul, Minn, has been appointed Superintendent of the School for Feeble-Minded at Faribault, Minn, by the State Board of Control

Dr Byrl R Kirklin (Fellow), Rochester, Minn, Professor of Radiology in the University of Minnesota Graduate School of Medicine (Mayo Foundation), and Dr Harry M Weber received the first award for their exhibit at the International Con-

gress of Radiologists at Chicago during September Dr Kirklin was elected President of the Roentgen-Ray Society

Dr Thomas B Magath (Fellow), Rochester, Minn, Professor of Parasitology in the University of Minnesota Graduate School of Medicine (Mayo Foundation), has been elected President of the American Society of Clinical Pathologists Dr Magath is the City Health Officer in Rochester

Dr Henry L Ulrich (Fellow), Minneapolis, Minn, Professor of Medicine at the University of Minnesota Medical School, has been installed as President of the Hennepin County Medical Society

Dr J Richards Aurelius (Fellow), St Paul, Minn, and Dr Louis E Prickman (Associate), Rochester, Minn, have been elected Secretary and Treasurer, respectively, of the Alumni Association of the Mayo Foundation

Dr Horton Casparis (Fellow), Nashville, Tenn, Professor of Pediatrics, Vanderbilt University Medical School, and Dr Julius H Hess (Fellow), Chicago, Ill, Professor of Pediatrics, University of Illinois Medical School, were guest speakers on the postgraduate symposium on Diseases of Women and Children held at Duke University, Durham, N C, November 11 to 13

Dr Douglas Martin (Fellow), Tampa, Fla, and Dr Warren W Quillian (Fellow), Coral Gables, Fla, have been elected President and Secretary, respectively, of the Florida Pediatric Society

Dr Oliver B Kiel (Fellow), Wichita Falls, Tex, has been elected President of the Texas State Board of Medical Examiners

Dr Edgar M Dunstan (Fellow), Dallas, Tex, has been appointed Superintendent of the Dallas City and County Hospital System

Dr Walter E Vest (Fellow and Governor), Huntington, W Va, has been elected President of the Public Health Council of West Virginia

Dr E H Shuller (Associate), McAlester, Okla, has been elected President of the Southeastern Oklahoma Medical Association

Dr Priscilla White (Fellow), Boston, Mass, was one of the guest speakers at a scientific meeting of the Georgia Pediatric Society at Atlanta, December 9

Dr Samuel A Levine (Fellow), Boston, Mass, Professor of Medicine, Harvard Medical School, and Dr Cyrus C Sturgis (Fellow), Ann Arbor, Mich, Professor of Medicine and Director of the Simpson Memorial Institute for Medical Research, University of Michigan were guest speakers on the program of the Oklahoma City Clinical Society's Conference, November 1 to 4, 1937

The Twelfth Series of Friday Afternoon Lectures sponsored by the New York Academy of Medicine for 1937-38 is made up, in part, by the following November 19, 1937—Dr Robert L Levy (Fellow), New York, N Y—"Drugs in the Treatment of Heart Disease", December 17, 1937—Dr Eugene M Landis (Fellow), Philadelphia, Pa—"Recent Advances in the Diagnosis and Treatment of Peripheral Vascular Diseases", January 7, 1938—Dr Rufus Cole (Fellow), Mount Kisco, N Y—"Treatment of Pneumonia", February 18, 1938—Dr William Thalhimer (Fellow), New York, N Y—"Convalescent Measles and Scarlet Fever Serums Their Value in Prophylaxis and Therapy", March 4, 1938—Dr Milton A Bridges (Fellow), New York, N Y—"The Evaluation of Recent Therapeutic Procedures", March 11 1938—Dr Thomas T Mackie (Fellow), New York, N Y—"Various Types of Colitis, with Particular Reference to Ulcerative Colitis", March 18, 1938—Dr James Ralph Scott (Fellow), New York, N Y—"The Modern Treatment of Diabetes Mellitus"

Dr Edward S Sledge (Fellow) President of the Alabama State Medical Association, addressed the Gulf Coast Clinical Society at Biloxi, Miss, on November 3 on "The Clinical Value and Limitations of Electrocardiography"

Other Fellows who contributed to the program were Colonel Charles F Craig, New Orleans, La, Dr Horton R Casparis, Nashville, Tenn, Dr William C Chaney, Memphis, Tenn, Dr Ray M Balyeat, Oklahoma City, Okla

Dr Lewis M Hurxthal (Fellow), Boston, Mass, was a guest speaker on the program of the Medical Institute of the University of Toledo on November 19, 1937

Dr Walter F Donaldson (Fellow), Pittsburgh, Pa, has been reelected Secretary of the Medical Society of the State of Pennsylvania

Dr Russell L Haden (Fellow), Cleveland, Ohio, and Dr William D Stroud (Fellow and Treasurer), Philadelphia, Pa, were among the guest speakers on the program of the Post-Graduate Medical Assembly of South Texas, at Houston, November 2 to 4

The Annual Congress of the Pan American Medical Association will be held January 15-31, 1938, aboard the S S Queen of Bermuda, on a cruise to Havana, Port au Prince, Trujillo City and San Juan Among chairmen of sections are the following Colonel Charles F Craig (Fellow), New Orleans, La—"Tropical Medicine", Dr Jay A Myers (Fellow), Minneapolis, Minn—"Thoracic Section", Dr Howard R Hartman (Fellow), Rochester, Minn—"General Medicine", Dr Edwin

C Ernst (Fellow), St Louis, Mo—"Radiology", Dr Orville E Barbour (Fellow), Peoria, Ill—"Pediatrics"

Dr Henry A Luce (Fellow), Detroit, Mich, is President-Elect of the Michigan State Medical Association

Dr Charles E Sears (Fellow), Portland, Ore, is President-Elect of the Oregon State Medical Society

Dr Raymond G Taylor (Fellow), Los Angeles, Calif, is President-Elect of the Radiological Society of North America

Dr Carleton B Peirce (Fellow), Ann Arbor, Mich, is Secretary of the American Roentgen-Ray Society

Dr Walter C Swann (Fellow), Huntington, W Va, was elected President of the Cabell County Medical Society for the year, 1938

Research Fellowships Available Fellowships in the medical sciences for the year beginning July 1, 1938, have been announced by the National Research Council. Fellowships are open to citizens of the United States and Canada who have the degree of doctor of medicine or doctor of philosophy. The Fellowships are intended primarily for recent graduates, and not for persons already established professionally. Applications should be filed by January 1, 1938. Appointments will be made at a meeting of the Medical Fellowship Board about March 1, 1938. Additional information may be obtained from the Secretary of the Medical Fellowship Board, National Research Council, 2101 Constitution Avenue, Washington, D C

REGIONAL MEETING OF VIRGINIA MEMBERS

A Regional Meeting of the Fellows and Associates of the American College of Physicians residing in Virginia was held, in connection with a Banquet, at the Shenandoah Club, Roanoke, Va, October 12, 1937, with twenty-six members present.

The Virginia members have organized their group under a local President and Secretary. Dr J W Preston, of Roanoke, was elected President of the local chapter to succeed Dr W B Martin, and Dr George B Lawson, of Roanoke, was elected Secretary to succeed Dr F C Rinker.

There was a general discussion concerning the present method of distributing inquiry cards to all Fellows concerning new candidates. The By-Laws of the College, Article V, Section 2, after covering the method by which a candidate shall be nominated, states "Further, the name of the candidate shall be sent to each Fellow in the candidate's locality, with a request for comments as to the candidate's fitness." This has been accomplished through cards sent out from the Office of the Executive Secretary after the receipt of each proposal.

A resolution was adopted referring to the Board of Regents, through the Executive Secretary, the recommendation that this system be changed, and in its

place a system adopted whereby regional committees shall be appointed, consisting of about four or five members located in different sections of each state, whose duty it shall be to investigate and reply to all letters of inquiries in regard to eligibility of new members

A further resolution was adopted that the Virginia Chapter of the College hold two regional meetings per annum, one at the Medical College of Virginia, in Richmond and the other at the University of Virginia, at Charlottesville

CORRECTIONS, 1937 DIRECTORY

It is regretted that two errors have been made in the names of Fellows of the College in connection with our biographical listing in the 1937 Directory. It is requested that members of the College reading this notice will kindly record these corrections in their directories.

Page 386, JORDAN, Sara Murray (the spelling J-o-r-d-o-n is incorrect)

Page 425, MACCRACKEN, Walter H. (the spelling, M-a-c-C-r-a-c-k-e-n is incorrect)

OBITUARIES

DR JOHN L CHESTER

Dr John L Chester (Fellow) of Detroit, Michigan, died May 31, 1937

Dr Chester was born in New York State, but came with his family to Michigan at an early age. He received his medical degree from Saginaw Valley Medical College in 1901, and started practice in Emmet, Michigan. In 1917, he moved to Detroit and practiced there until the time of his death, confining his practice to Internal Medicine. His work was largely in the field of cardiology, on which subject he published a number of papers.

Dr Chester held staff positions at Providence Hospital (Chief-Elect), and at Seymour Hospital, Eloise, in which institution he was Physician in Chief, Division of General Medicine. He was active in teaching, and held appointment as Professor of Clinical Medicine in Wayne University College of Medicine. He was a Fellow of the American College of Physicians since 1926.

Dr Chester was a very earnest student in his field, and his death will be a great loss to his large practice, as well as to the profession. He was active in all local medical society activities, read many papers before medical groups, and took a particularly keen interest in the internes and younger members of the profession, whom he was always ready to help with counsel and advice. The profession has lost an able clinician and a good friend.

HENRY R CARSTENS, M D , F A C P ,
Governor for Michigan

DR ISAAC IVAN LEMANN

Dr Isaac Ivan Lemann (Fellow, 1920) of New Orleans, who was born at Donaldsonville, Louisiana, 1877, and died on September 2, 1937, will be sadly missed not only by the members of the medical profession of New Orleans and the State of Louisiana but by his many friends and admirers throughout the Nation.

Dr Lemann was gentle and modest in his relations with other members of the profession. He was especially considerate and charitable toward the younger members of his profession. He was admired and loved by the student bodies of the institutions with which he was connected. Dr Lemann made many valuable contributions to medical literature, outstanding among these was his work and published papers on diabetes. He was recognized as a clinician of superior ability, and personally a most lovable individual.

Dr Lemann received the A B degree from Tulane University in 1895, A B from Harvard University in 1896, M D from Tulane University of Louisiana School of Medicine in 1900. Instructor in Clinical Medicine, Tulane University of Louisiana School of Medicine, 1906-1910, Assistant

Professor of Clinical Medicine, Tulane University of Louisiana School of Medicine, 1910-1914, Professor of Clinical Medicine, Tulane University of Louisiana School of Medicine, 1914-1937, Chief of Medical Service, Touro Infirmary, New Orleans, Consultant in Medicine, Charity Hospital, New Orleans, Senior Consultant in Medicine, Flint Goodridge Hospital of Dillard University, Vice Chairman of the Section on Practice of Medicine, American Medical Association, 1932-1933, Fellow of the American College of Physicians since 1920, Member Orleans Parish Medical Society, Louisiana State Medical Society, American Medical Association, Southern Medical Association, American Society of Tropical Medicine, Southern Inter-urban Clinical Club, Association of American Physicians, and the American Clinical and Climatological Association

The College has suffered a severe loss in the passing of Dr Lemann and he will be sorely missed as a Member of the faculty of Tulane University and in relation to his hospital connections

J E KNIGHTON, M D , F A C P ,
Governor for Louisiana

DR HARRY GILMER WALCOTT

Dr Harry Gilmer Walcott (Fellow 1928), aged sixty, a native Texan, died June 2 1937, in a Dallas hospital after a long illness

Dr Walcott was a descendant of pioneer Texas stock His academic education was obtained at Austin College in Sherman, Texas, and the Holbrook Normal School in Tennessee In 1901 he graduated with high honors from the Baltimore Medical College, where he remained as Associate Professor of Physiological Chemistry for one year He then returned to his old home at Honey Grove Texas, where he engaged in practice until April 1903, when he went to Chicago for a period of study under an association with the late Dr Fenton B Turck While in Chicago Dr Walcott gave particular attention to the study of disorders of digestion Later in 1903 he moved to Dallas Texas, to enter the practice of gastro-enterology He was the first physician in the state to practice this specialty exclusively, and was throughout the years a recognized leader in his section For a period of years he was professor of gastro-enterology in Baylor Medical School, and at the time of his death was an emeritus professor Perhaps to Dr Walcott more than to any other person belongs the credit for the placing of gastro-enterology on a high plane in Texas

During the World War he served with distinction as a Captain in the Medical Corps of the United States Army

To those who knew him best Dr Walcott exemplified and practiced the highest ethical tenets of the profession He was zealous of the welfare of his patients affectionate and indulgent with his family, a loyal friend and a wise counselor to those who sought his opinion and advice

He is survived by his wife, a son, Harry Gilmer Walcott, Jr., and a daughter, Mrs William Lipscomb

CHARLES T. STONE, M D, F A C P,
Governor for Texas

DR ELIJAH LUMBIA MASON

Dr Elijah Lumbia Mason was born February 25, 1871, in Rocky Mount, Virginia, the son of Gilbert and Susan Goode Mason, of Virginia. He was educated in private schools. He was a resident of the District of Columbia since 1894. He was graduated in pharmacy from the National College of Pharmacy, 1896, and was graduated in medicine from Columbian (now George Washington) University, 1901.

Dr Mason was married to Viola V. Hines of Virginia in 1906, and they had one child, Jack Wellons Mason. His wife and son survive him.

Dr Mason was a member of the following organizations: Fellow of the American Medical Association, Fellow of the American College of Physicians, Medical Association of the District of Columbia, April 2, 1902, Medical Society of the District of Columbia, October 1, 1902 (Seniority Number 298), the Hippocrates-Galen Society, of which he was a past president, the Phi Sigma Kappa Fraternity. He was consulting physician to the Washington City Orphan Asylum, and to the Episcopal Eye, Ear and Throat Hospital. He was associate in Medicine of the Garfield Memorial Hospital.

He was connected with the Children's Hospital as pharmacist and after graduation in medicine as resident physician and pathologist.

On September 5, 1932, following an accident at Gallinger Municipal Hospital, he was totally incapacitated for practice. He died on August 30, 1937, as the result of bronchopneumonia.

It is difficult to draw any valid conclusions from such meager data, as to the character and life of Dr. Mason. But from those who came in contact with him for the more than forty years of his activities in Washington the record can be fully made up. Quiet and courteous in his dealings with others, conscientious and thorough in his professional work, gracious and kindly with his friends, always a gentleman. Such characters are an inspiration to those coming in contact with them, and to those coming after. His passing is a distinct loss to the profession.

V. B. JACKSON, Chairman,
J. D. THOMAS and F. R. HAGNER,
Committee

(Presented before the Medical Society of the District of Columbia, November 10, 1937.)

ANTI-PNEUMOCOCCIC SERUM

Refined and Concentrated Globulin

MINIMUM Volume

of the whole serum, with a decrease of inert solids and proteins

The Research Laboratories of The National Drug Company have made intensive studies of producing and refining Pneumonia Serums. Methods of immunizing horses, and improved processes, enable us to offer a standardized serum, with 1/6 the volume of the whole serum, with a proportional decrease of non-essential serum proteins.

Monovalent Anti-Pneumococcic Serum (National) Type I contains
10,000 Type I Units in Syringe

Bivalent Anti-Pneumococcic Serum Type I and II contains
10,000 Type I Units and 10,000 Type II Units in Syringe

The Serum is Standardized in Felton-International Units

Furnished in perfected syringes with chromium (rustless steel) needles

The Serum Should Be Given Every 6 to 8 Hours

Send literature on Anti-Pneumococcic Serum

ANNALS OF INTERNAL MEDICINE

OFFICIAL PERIODICAL OF THE AMERICAN COLLEGE OF PHYSICIANS

Place of Publication—Prince and Lemon Sts, Lancaster, Pa

Editorial Office—University Hospital,
Baltimore, Md

Executive Office—4200 Pine Street,
Philadelphia, Pa

THE ANNALS OF INTERNAL MEDICINE is published by the American College of Physicians. The contents consist of contributions in the field of internal medicine, editorials, book reviews, and a section devoted to the affairs of the College.

MANUSCRIPTS All correspondence relating to the publication of papers and all books and monographs for review should be addressed to the editor. No manuscripts will be accepted without his consideration. Bibliographic references are to conform to the following style:

4 DOE, J. E. What I know about it, Jr. Am Med Assoc, 1931, xcvi, 2006-2008.

Six illustrations per article are allowed without cost to the author. Beyond this number the author must pay the actual cost of illustrations.

REPRINTS For each article published, there will be furnished gratis fifty reprints without covers. An order slip for additional reprints, with a table showing cost, will be sent with galley proof to each contributor. If additional reprints over the first fifty are wanted the order slip must be returned to the printer at the time corrected galley proofs are sent to the Editor.

REVIEWS The ANNALS will make an especial feature of the reviews of monographs and books bearing upon the field of internal medicine. Authors and publishers wishing to submit such material should send it to the editor. While obviously impossible to make extended reviews of all material, an acknowledgment of all books and monographs sent will be made in the department of reviews.

SUBSCRIPTION This periodical is issued monthly, new volumes beginning with the July number each year. Subscriptions may be by the volume or year, but the volume basis is especially recommended. Volumes will consist of approximately 1,400 pages. Subscription price per volume, or per annum, net postpaid: \$7.00, United States, Canada, Mexico, Cuba, Canal Zone, Hawaii, Porto Rico, \$7.50, other countries. Prices for back volumes or numbers furnished upon application. Single numbers, current volume, when available, \$1.00. Members of the American College of Physicians receive the ANNALS OF INTERNAL MEDICINE as a part of their membership. Checks should be drawn to the order of W. D. STROUD, M.D., Treasurer, and remitted through the Publication Office or the Executive Secretary's Office.

BUSINESS CORRESPONDENCE All correspondence relating to business matters, advertising, subscriptions to the ANNALS, inquiries concerning membership in the American College of Physicians, et cetera, should be addressed to the Publication Office or to the Executive Secretary. Books and reprints presented to the College Library should be addressed to the Executive Secretary.

22nd ANNUAL SESSION—NEW YORK

Not a New Year's
Resolution, But...

The Lilly Code

in Practice Every Day for Sixty-One Years

- 1 To provide the profession with medicinal products of highest quality and unvarying potency.
- 2 To contribute to the progress of medicine by developing new and superior agents through research
- 3 To issue information about the uses of the products of the company through professional channels exclusively.

EPHEDRINE PREPARATIONS, LILLY

• Since the original commercial development of ephedrine by Eli Lilly and Company eleven years ago, new uses for this important drug have appeared and suitable preparations of ephedrine have been

made available for each new indication

A thirty-six-page booklet describing these indications and listing Ephedrine Products, Lilly, will be sent to physicians upon request

NEW WORKS FOR

BIOLOGICAL AND CLINICAL CHEMISTRY

By **MATTHEW STEEL, Ph D**

Professor of Biochemistry in the Long Island College of Medicine, Brooklyn, New York

Octavo, 770 pages, illustrated Cloth, \$8 00, net

This book is unique in its comprehensiveness, including in a single volume the essentials of theoretical biological chemistry, practical biological chemistry, biophysics and quantitative clinical chemistry To obtain these data the purchase of three or four volumes has hitherto been necessary The work presents the theoretical clinical aspects of pathological conditions, the most difficult phase of the modern course in biochemistry While intended primarily for classroom use, the book is equally valuable to the physician

DIETETICS FOR THE CLINICIAN

By **MILTON A BRIDGES, M D , F A C P**

Assistant Professor of Clinical Medicine and Lecturer in Therapeutics and Nutrition New York Post-Graduate Medical School, Columbia University, New York

Third edition Octavo, 1055 pages Cloth, \$10 00, net

This enlarged and thoroughly revised edition of an unusually successful work is practically a new book on the latest information in this field It covers a new classification of foods, including their values in their edible state as well as the analyses of raw products It has been enlarged to include the dietary treatment of more than 200 diseases and the diets themselves have been increased to 300, with approximately 900 menus The appendix now includes over 200 pages of tables In its present form, it will be found far more comprehensive, better organized and more efficient than ever

Only 1/5th of the mighty iceberg glistens above the surface of the sea, but it is the huge unseen part below the surface that counts most.

LIKEWISE in the Hindle Electrocardiograph, the more important parts do not meet the eye. You can see the beautiful finish of the cabinet, the galvanometer simplicity and the convenient instrument panel layout. You are conscious through surface indications of fine materials and precision workmanship. but you cannot see the twenty-

five years of experience in designing and building of fine cardiac diagnostic instruments that makes the Hindle the standard of comparison.

The Hindle is more than a piece of medical equipment—it is the summation of experience since the inception of Electrocardiography, translated into a fine instrument by Cambridge craftsmen.

What does this mean to you? an instrument which will produce accurate results during a lifetime of satisfactory service—witness the first instrument of twenty-five years ago still performing perfectly in a world-famous hospital!

Announcing

PERTUSSIS ANTIGEN

(Detoxified)

Lederle

THIS new form of therapy is recommended for the treatment of active cases of Whooping Cough as well as for general prophylaxis

Free from bacterial cells, Pertussis Antigen (Detoxified) *Lederle* is a departure from the usual form of vaccine therapy. Based upon a toxic principle derived from *H. pertussis*, treatment with formalin converts the toxic factor into a non-toxic substance having antigenic properties.

If used early in *treatment* or soon after exposure, the immunological response is sufficiently rapid to modify or prevent, respectively, the disease in the majority of cases, as evidenced by the following

49 of 53 cases treated during the first or second week did not develop whooping or vomiting

Of 70 cases treated during the third or fourth week, 30 became symptom-free after the completion of injections, while the remainder showed marked improvement but continued to run a mild, modified course of whooping cough. Cases treated during the fifth week showed no benefit.

When used for *prevention*, only 3 out of 140 developed the disease and those 3 were mild atypical cases.

Packages
3 vials—2 cc. each
1 vial—20 cc.

LEDERLE LABORATORIES, INC.

NEW YORK, N. Y.

Announcing VI-DELTA EMULSION

Lederle

(VITAMINS A AND D)

ALTHOUGH IT IS more potent in Vitamins A and D than Cod Liver Oil, U S P XI, this new emulsion has

- no fish-oil taste
- no after-taste
- nor does it cause flatulence

On the contrary, it tastes like orange syrup and children lick the spoon and beg for more. It can be flooded over ice cream to make an orange sundae and unsuspecting guests will pass their plates for second helps—it's been done!

The special feature is the new fish liver oil concentrate, derived from various fish (excluding cod) and balanced to a uniform high potency of Vitamins A and D. Unlike cod liver oil, whose inherent rank taste bursts through all disguises, this concentrate is practically tasteless, the flavor of the emulsion is only that of the materials with which it is blended malt, sugar and natural orange juice.

To conform with familiar dosage practice, Vi-Delta is so balanced that each teaspoonful (4 cc — 5.2 gram) contains 3200 units U S P XI Vitamin A and 400 units U S P XI Vitamin D, same as "cod liver oil N N R and exceeding "cod liver oil U S P XI" (which has 2180 A, 313 D)

Packages

8 oz. and 16 oz. bottles

DIABETICS

LIVE LONGER

Today

THE LIFE SPAN of the diabetic has been lengthened considerably following the discovery of Insulin and the growing knowledge of its use. There is, however, a definite responsibility on the part of the physician to educate the many new diabetics in the importance of proper diet and proper use of Insulin preparations.

The apparent increase in diabetes in recent years has been attributed to the modern manner of living, increased sugar consumption, overeating and lack of muscular exercise. With proper management the great majority of patients can be kept well-nourished, sugar-free, and at work.

Insulin Squibb is an aqueous solution of the active anti-diabetic principle obtained from pancreas.

It is accurately assayed, uniformly potent, carefully purified, highly stable and remarkably free of pigmentary impurities and proteinous reaction-producing substances.

Insulin Squibb of the usual strengths is supplied in 5-cc and 10-cc vials.

Protamine Zinc Insulin, Squibb complies with the rigid specifications of the Insulin Committee, University of Toronto, under whose control it is manufactured and supplied. It is available in 10 cc vials. When this preparation is brought into uniform suspension, each cc contains 40 units of Insulin together with protamine and approximately 0.08 mg of zinc.

SAFETY

During Oral Therapy of Urogenital Infections—paramount considerations confronting the physician are—

SAFETY and EFFECTIVENESS

Pyridium is established as a safe and effective remedy in the treatment of urogenital infections

Pyridium, orally, is effective in promptly relieving distressing symptoms of cystitis, pyelitis, prostatitis, and urethritis, such as, painful and frequent urination, tenesmus and referred lumbar pain

MERCK & CO. INC *Manufacturing Chemists* RAHWAY, N. J.

For Children's Colds

In prescribing 'Benzedrine Inhaler' for children's head colds, you are providing a first aid remedy which may prove of constant service.

At the first sign of a cold the child is instructed to use the inhaler. Since benzyl methyl carbamine is volatile, it penetrates to areas not readily accessible to liquid inhalants, and there is no oil to be aspirated and become a potential source of later trouble by accumulating in the lungs (Graef—Am J of Path., Vol. xi No. 5, Sept 1935)

For the adult members of the family, 'Benzedrine Inhaler' is equally useful.

Each tube is packed with benzyl methyl carbamine 325 gm oil of lavender 097 gm menthol 032 gm

'Benzedrine' is the trade mark for S. K. L. Surgical Inhaler and for their brand of the substance whose descriptive name is benzyl methyl carbamine

★ DISCIPLINE ★

"Discipline is the development of the faculties by instruction and exercise " When functions such as habit time of bowel movement are neglected through lack of discipline or intelligence, they require careful training to restore them to a normal state Petrolagar has proved to be an agreeable and effective means of establishing bowel discipline Because Petrolagar mixes intimately with the bowel contents, it increases the bulk in the stool to a soft mass which is easily passed The Five Types of Petrolagar provide the doctor with a variation of treatment to suit the individual patient Petrolagar Laboratories, Inc , 8134 McCormick Boulevard, Chicago, Illinois

Petrolagar — Liquid petrolatum 65 cc emulsified with 0.4 Gm agar in a menstruum to make 100 cc

Petrolagar

NEO-SYNEPHRIN HYDROCHLORIDE

(laevo alpha-hydroxy beta-methyl-amino-3-hydroxy ethylbenzene hydrochloride)

No doubt the first thought of the patient who is suffering from nasal congestion due to the common cold, rhinitis, or other upper respiratory tract infection, is "How can I obtain relief from this 'stuffed-up' condition and be enabled to breathe freely?"

You can not only provide the desired symptomatic relief quickly, but you can assure a prolonged decongestive effect by the topical application of the synthetic vaso-constrictor, Neo-Synephrin Hydrochloride

Whether you apply Neo-Synephrin by dropper, spray, jelly or applicator, you will find that all forms are without sting, that they not only give a more sustained action, but are better tolerated than either epinephrine or ephedrine, and that in the dosage recommended, they do not usually produce "nervousness" or insomnia

Neo-Synephrin can be used equally well for *either adults or children* in these convenient forms—

EMULSION

¼% (1 oz bottle with dropper)

SOLUTION

¼% for dropper or spray

1% for resistant cases

(1 oz bottles)

JELLY

½% (in collapsible tubes with applicator)

NOTE For Acute Hypotension due to shock or anesthesia especially spinal, the subcutaneous administration of Neo Synephrin Hydrochloride has been found of established merit. For this purpose, Neo Synephrin is supplied in rubber capped vials containing 15 cc of a sterile 1% solution

KNOX CLINICAL NOTES

ONE OF A SERIES OF CORRESPONDENCE EXCHANGES WITH PHYSICIANS ABOUT KNOX GELATINE.

The Glycine Content of KNOX GELATINE

A physician writes, "Pertaining to Glycine—glycocoll $\text{NH}_2\text{CH}_2\text{COOH}$ —gelatine contains large amounts of Glycine I feed a great deal of Knox Gelatine to patients suffering from fatigability—'muscle exhaustion'—with very good results in conjunction with the administration of 15 to 30 grams of Glycine given daily Glycine is rather expensive to patients—about eight dollars per pound I wish to know the percentage of Glycine in your best grade Knox Gelatine so I may substitute more liberal feedings of Knox Gelatine and cut the pure Glycine dosage down to a lower and more economical level."

The KNOX GELATINE LABORATORY Replied as Follows:

Thank you, Doctor! You are right about Knox Gelatine. Increasing amounts of it are being fed in asthenic conditions. Knox Gelatine contains 25% of amino-acetic acid (Glycine). Goodly amounts can be fed in soups, broths, and other recipes to supply amounts of Glycine in this palatable gelatine form which is so economical. Perhaps the simplest way to feed it is as

follows: have the patient dissolve the contents of one of the envelopes from the Knox Gelatine package in a little warm water and then fill the glass with cold fruit juice. It is a palatable drink which gives the patient about seven grams of pure gelatine. As many as 4 envelopes can be taken at one time, as often as needed during the day.

Why you should insist on Knox Sparkling Gelatine

Because Knox Gelatine is 85% protein in an easily digestible form—because it contains absolutely no sugar or other substances to cause gas or fermentation, Knox Gelatine should not be confused with factory-flavored, sugar-laden dessert powders. Knox is 100% pure USP gelatine. Knox Gelatine has been successfully used in the dietary of convalescents, anorexic, tubercular, diabetic, colitic, and aged patients.

KNOX SPARKLING GELATINE
IS PURE GELATINE—NO SUGAR
KNOX GELATINE LABORATORIES
JOHNSTOWN, NEW YORK

Calm Sleep - Bright Awakening

To the patient exhausted by persistent insomnia, restful and refreshing sleep is a tonic both to mind and body

In the common types of nervous insomnia, the administration of Phanodorn is followed by sleep closely approximating the normal. There is no harmful effect on respiration or cardiac function. After an adequate period of sound sleep the patient usually awakens without a hangover of drowsiness, dulness, headache, dizziness.

An increasing number of physicians are adopting Phanodorn as the hypnotic of choice for everyday practice. Its field of indications includes insomnia associated with neurasthenia and other neuroses as well as sleeplessness during the course of acute and chronic organic diseases.

Dose: 1 tablet at bedtime, preferably with warm drink, increased to 2 tablets in obstinate insomnia.

Sample and literature on the action and therapeutic indications of Phanodorn will be sent to physicians on request.

Medical skill and good nursing care are essential

*and so is
Sleep*

ONE THING the patient requires and not the least essential—is sleep. By restoring the physical resources of the body, sleep often turns the tide in favor of recovery.

When sleep is difficult, the physician may prescribe Tablets Ipral Calcium with assurance of safety. A small therapeutic dose produces restful sleep closely resembling the normal, from which the patient awakens generally calm and refreshed. Ipral Calcium is readily absorbed and rapidly eliminated. Undesirable cumulative effect may be avoided by proper regulation of the dosage. No digestive disturbance or untoward organic effects have been reported.

IPRAL CALCIUM (calcium ethylisopropylbarbiturate) is supplied in 2-gr tablets and also in powder form—for use as a sedative and hypnotic.

IPRAL SODIUM (sodium ethylisopropylbarbiturate) is supplied in 2-gr capsules for hypnotic use and in 4-gr tablets for preanesthetic medication.

IPRAL CALCIUM (Powder) is available in 1-oz bottles. Tablets Ipral Calcium 2 gr, Tablets Ipral Sodium 4 gr, and Capsules Ipral Sodium 2 gr are available in bottles of 100 and 1000.

NEO-SILVOL

Neo-Silvol (Colloidal Silver Iodide Compound) is par-
ticularly useful for eye, ear, nose and throat. In-
cluding the treatment of acute and chronic otitis
media, sinusitis and tonsillitis. In a 25 to 50
per cent solution Neo-Silvol will not injure delicate
mucous membranes.

Ten to twenty per cent solution of Neo-Silvol are
suitable for most eye conditions. For more severe
may call for stronger solutions—25 to 50 per cent. In

inflammatory conditions of the nose, naso-pharynx,
pharynx and tonsils, Neo-Silvol (10 to 25 per cent
strength) may be sprayed or swabbed on the involved
areas three or four times daily. Neo-Silvol solutions
are easily prepared by dissolving the glistening, cream-
colored granules in water.

Supplied in six-grain capsules, packages of 50 and
500, and in 1-ounce and 1/4-pound bottles.

PARKE, DAVIS & COMPANY, DETROIT The World's Largest Makers of Pharmaceutical and Biological Products

VITAMINS and TASTE

One of the reasons why so many physicians prescribe vitamins A and D in the form of MALTINE WITH COD LIVER OIL is that this preparation has none of the unpleasant oily consistency and taste usually associated with vitamin-bearing oils. Patients—even small children—enjoy it. Furthermore, the vitamin-A efficiency of cod liver oil is actually *enhanced two-fold* when emulsified with Maltine, as has been proved by carefully checked laboratory experiments. In addition to the vitamins of cod liver oil, this preparation also contains the valuable factors of Maltine.

Another preparation, MALTINE WITH COD LIVER OIL and IRON IODIDE, is also available, with a concentration of two grains of freshly prepared iron iodide per fluid ounce. . . . The Maltine Company, 60 Hudson Street, New York City.

WITH COD LIVER OIL

INTRODUCED 1875

For bland diet therapy, especially ULCER cases — PABLUM

FAR too often the bland diet prescribed for gastric ulcer, colitis, and similar gastro-intestinal disorders is a deficient diet. An analysis made by Troutt of ulcer diets used by 6 leading hospitals in different sections of the country showed them to be "well below the Sherman standard of 15 milligrams" in iron and low in the water-soluble vitamins.¹ "Vitamin B would appear to be represented at a maintenance level in most cases," writes Troutt, "but the possible relation of vitamin B to gastro-intestinal function and appetite should make one pause before accepting a low standard."

Although Pablum has a low fiber content it is 37 times richer than farina in iron and in calcium 4 times richer in phosphorus and $4\frac{1}{2}$ times richer in copper.

Low in Fiber — High in Iron

Pablum is the only food rich in a wide variety of the accessory food factors that can be fed over long periods of time without danger of gastro-intestinal irritation. Its fiber content is only 0.9%. Yet Pablum contains 37 times more iron than farina and is an excellent source (+ + +) of vitamins B and G, in which farina is deficient. Supplying $8\frac{1}{2}$ mgms iron per ounce, Pablum is 8 times richer than spinach in iron.

Rich in Vitamin B

The high vitamin B content of Pablum assumes new importance in light of recent laboratory studies showing that avitaminosis B predisposes to certain gastro-intestinal disorders. Apropos of this, Cowgill says, "Gastric ulcer is another disorder which can conceivably be related to vitamin B deficiency. Insofar as the treatment of this condition usually involves a marked restriction of diet the occurrence of at least a moderate shortage of this vitamin is by no means unlikely. Obviously the length of the period of dietary restriction is an important determining factor. Dalldorf and Kellogg (1931) observed in rats subsisting on carefully controlled diets that the incidence of gastric ulcer was greatly increased in vitamin B deficiency. Observations of this type merit serious consideration."²

Requiring no further cooking, Pablum is especially valuable during the healing stage of ulcer when the patient is back at work but still requires frequent meals. Pablum can be prepared quickly and conveniently at the office or shop simply by adding milk or cream and salt and sugar to taste. Pablum has the added advantage that it can be prepared in many varied ways—in muffins, mush, puddings, junket, etc. Further, Pablum is so thoroughly cooked that its cereal-starch has been shown to be more quickly digested than that of farina, oatmeal, cornmeal, or whole wheat cooked four hours in a double boiler (studies *in vitro* by Ross and Burrill).

In addition to all the above points Pablum has the advantage of being the only base-forming cereal (except Mead's Cereal which is the uncooked form of Pablum).

Pablum consists of wheatmeal, oatmeal, cornmeal, wheat embryo, alfalfa, yeast, beef bone, iron salt and sodium chloride

THE TREATMENT OF RHEUMATOID ARTHRITIS WITH AN INJECTABLE FORM OF BEE VENOM *

By JACQUES KRONER M D , ROBERT M LINTZ, M D , MARION TYNDALL,
M D , LEONORA ANDERSEN, M D , and EDITH E NICHOLLS, M D ,
New York, N Y

FOR many generations there has been prevalent among the rural population of European countries and to a lesser extent in America, a belief that the sting of bees is a cure for rheumatism Beck,¹ in 1935, published a book on this subject and he traced the use of bee sting and bee venom from antiquity up to the present time Bee-keepers were the first to use bee sting in the treatment of rheumatic conditions and it is only within the past 50 years that physicians have adopted it as a therapeutic measure The first medical report of its use for rheumatoid arthritis was published in 1859 by Demartis² of Bordeaux Terč,³ in Austria in 1880, was the first to use bee sting in his practice as a form of therapy for rheumatoid arthritis and neuritis, and he so treated a large number of patients He published several favorable reports concerning its value but was unable to arouse much enthusiasm among the members of the medical profession During the past 30 years bee sting therapy has been used in European countries with increasing favor

In 1928, Pollack,⁴ in Munich, and Kretschy⁵ in Vienna produced an injectable form of bee venom This product is now made in the chemical laboratories of Dr August Wolff in Bielefeld, Germany, under the name of "Apicosan" The composition and method of preparation of "Apicosan" have not as yet been published, but the authors claim that it "contains the natural secretion of the honey bee in physiological saline solution" Favorable reports of its use for the various forms of rheumatism have been published by physicians in Berlin, Vienna and Geneva

* Received for publication March 10, 1937

From the New York Hospital, and the Department of Medicine of Cornell University Medical College, New York City

The bee venom used in this experiment is a preparation called "Apicosan" manufactured by Dr August Wolff, Bielefeld, Germany, and dispensed in the United States through A W Kretschmar, Inc, New York City

Copyright, 1938 by The American College of Physicians

However, in spite of the many articles that have appeared on the use of bee venom for the treatment of rheumatism there is hardly one that presents evidence of a scientific application of this form of therapy. In most instances, the type of rheumatic disease studied is not clearly defined, the number of patients treated is small, and only generalized statements regarding the results are given.

PRESENT STUDY

The present study was undertaken in order to determine the merits of bee venom in an injectable form (*Apicosan*) in the treatment of rheumatoid arthritis. The patients included in this report were all ambulatory and were treated in the Arthritis Clinic of the New York Hospital. The patients were intelligent and cooperative and were permitted to pursue their usual occupations. An attempt was made to select only patients in whom a focus of infection had been removed some time previously, or in whom none had been found. A few patients were included, however, who had diseased tonsils, the removal of which was contra-indicated. Many of the patients had undergone various forms of therapy without relief.

The patients included in the present study were divided into four groups. One group comprises patients with a markedly active and advanced form of arthritis—deformities such as ulnar deviation and partial or complete ankylosis of one or more joints characterize this group. A second group includes patients presenting the typical picture of well developed rheumatoid arthritis with the characteristic periarticular swelling of the joints, usually including fusiform fingers. A third group comprises those who complained of severe pain in the joints but who failed to show any evidence of arthritis at the time of examination, other than tenderness and stiffness of the joints. In the tables these three groups have been represented by the symbols +++, ++, and +, respectively. All of these patients were found to have an elevated corrected sedimentation index on admission. There is a fourth group, similar to group three except for the fact that the patients had a corrected sedimentation index within the normal range.

Forms of treatment supplementary to the bee venom injections were limited to a minimum. An unrestricted diet, high in vitamins, was usually recommended. Acetyl salicylic acid was frequently prescribed for the relief of pain and patients were advised to apply heat to the affected joints. Cod liver oil was given in many cases.

One hundred patients were studied—25 male and 75 female. The youngest patient was 21 years of age and the oldest 74 years. Thirteen patients were under 30 years of age, fifty-seven ranged in age from 30 years to 50 years and thirty were over 50 years of age.

The duration of the arthritic symptoms ranged from three weeks to 60 years. Thirty-six patients had had arthritis for one year or less, 38 patients between two and five years, and 26 patients more than five years.

Because of the tendency of patients with rheumatoid arthritis, who have been relieved of their symptoms, to suffer relapses or to develop transitory pains in the joints, we have not classified any of our cases as *cured*, being content to use the word *improved*. Improvement was judged by a fall in the corrected sedimentation index, if previously elevated, and an alleviation of the clinical symptoms. Care was exercised not to confuse temporary changes due to climatic or other varying conditions with more lasting ones. No patient has been included who has not been under observation for at least two months and many have been followed for a year or more.

METHOD

All injections were given intradermally. The site selected depended upon the location of the most painful joints. The skin was cleaned with alcohol and wiped dry with benzene. *Apicosan* comes in four different concentrations: N, I, II and III. Strength N is a 1:10,000 dilution of concentration I. One c.c. of concentration I is said to contain the venom of one bee sting, 1 c.c. of concentration II, of three bee stings, and 1 c.c. of strength III, of nine bee stings.

The initial or test dose was 0.1 c.c. of concentration N, injected slowly intradermally forming a wheal. If no reaction followed this injection then 0.1 c.c. of concentration I was given, at the next visit. The treatments were continued at weekly or biweekly intervals, increasing 0.1 c.c. at each visit. Only 0.1 c.c. was put into a wheal and the wheals were placed about one inch apart. When a patient had received 0.5 c.c. of concentration I, or 5 wheals, he was given 0.1 c.c. of concentration II which was increased to 0.5 c.c. and then concentration III was started. The dose was then increased 0.1 c.c. at each visit until the patient was receiving one ampoule of concentration III. All injections were watched for five minutes. If large pseudopodia developed in the wheals, they denoted sensitivity and the dose was not increased for several visits. With one exception, only those patients were included in the study who had received six or more injections.

The sedimentation test used in this study was that recommended by Rourke and Ernstene,⁶ and the figure indicating the sedimentation rate is known as the *corrected sedimentation index*. An index of 0.4 or less was considered normal.

RESULTS

One hundred patients with rheumatoid arthritis were treated with intradermal injections of bee venom (*Apicosan*) and 73 showed definite improvement, as judged by a fall in the corrected sedimentation index and an alleviation of the clinical symptoms (table 1). Seventeen of these were found to be entirely free of symptoms six months to a year after the treatments were discontinued, 18 continued to have mild transitory pains only and 38 were moderately improved.

TABLE I

Results of Treatment with Bee Venom (*Apicosan*) of 100 Patients with Rheumatoid Arthritis

| Severity of Disease | Number of Patients | Markedly Improved | | Moderately Improved | | Total Improved | | Unimproved | |
|---------------------|--------------------|-------------------|----------|---------------------|----------|----------------|----------|------------|----------|
| | | Number | Per cent | Number | Per cent | Number | Per cent | Number | Per cent |
| +++ | 10 | 0 | 0 | 6 | 60 | 6 | 60 | 4 | 40 |
| ++ | 36 | 12 | 33 | 15 | 41 | 27 | 75 | 9 | 25 |
| + | 24 | 13 | 54 | 7 | 29 | 20 | 83 | 4 | 17 |
| +* | 30 | 10 | 33 | 10 | 33 | 10 | 66 | 10 | 33 |
| Total | 100 | | 35 | | 37 | | 73 | | 27 |

* = Patients having a corrected sedimentation index within the normal range

Ten of the patients studied had an advanced, active deforming type of arthritis and six of these showed moderate improvement. Thirty-six patients had severe pain and swelling of the joints and of these 12 showed marked improvement, 15, moderate improvement, while nine failed to respond to treatment. Twenty-four patients were treated who had severe pain and stiffness of the joints but no evidence of swelling at the time of examination and all but four showed improvement, 13 improving markedly, and seven moderately. Thirty patients had joint pains and stiffness similar to the above group but a corrected sedimentation rate within the normal range at the time of admission. Ten of these patients showed marked improvement, 10 moderate improvement, and 10 no improvement.

A patient was not considered improved unless there was a drop in the corrected sedimentation index, if previously elevated, as well as improvement in the clinical symptoms. In table 2 is shown the average corrected sedimentation index for the +++, ++, and + groups, before and after treatment, of the patients who improved as compared with those who failed to respond.

TABLE II

Effect of Treatment on the Corrected Sedimentation Index

| Severity | Average Corrected Sedimentation Index | | | |
|----------|---------------------------------------|-----------------|---------------------|-----------------|
| | Patients Improved | | Patients Unimproved | |
| | Before Treatment | After Treatment | Before Treatment | After Treatment |
| +++ | 1.43 | 0.92 | 1.28 | 1.38 |
| ++ | 1.18 | 0.71 | 0.90 | 1.03 |
| + | 0.73 | 0.45 | 0.91 | * |

* = Two of the four patients in this group failed to return for a repeat test

As might be expected, the average corrected sedimentation index was higher for the patients with more advanced arthritis. There were 10 in this group and the corrected sedimentation index before treatment ranged from 0.7 to 2.0, with seven having an index of 1.4 or higher. The corrected sedimentation rate for the patients with a moderately severe arthritis ranged from 0.5 to 1.6, with 80 per cent having an index of 1.0 or higher. For the patients showing a mild form of arthritis the corrected sedimentation index ranged from 0.4 to 1.4 with 75 per cent having an index of 1.0 or less. Following treatment there was a drop of five points in the average corrected sedimentation index for the patients showing improvement in the +++ and ++ groups and a drop of three points for the patients in the + group.

It was a matter of interest to compare the number of injections and duration of treatment of the patients who improved with those who did not. In treating ambulatory patients in a clinic it is difficult to control the number of visits. Many patients become discouraged and fail to return after a few visits. In table 3 is shown the average number of injections and average duration of treatment for the three groups of patients studied.

TABLE III

Relationship of Number of Injections and Duration of Treatment to Improvement

| Severity | Average Number of Injections | | Average Duration of Treatments | |
|----------|------------------------------|------------|--------------------------------|------------|
| | Improved | Unimproved | Improved | Unimproved |
| | | | (Months) | |
| +++ | 31.5 | 18.5 | 5.6 | 2.6 |
| ++ | 21.5 | 15.5 | 4.5 | 2.5 |
| + | 18.7 | 13.7 | 3.8 | 1.9 |
| +* | 14.5 | 15.9 | 3.2 | 3.5 |

* = Patients having a corrected sedimentation index within the normal range

Of the 10 patients with advanced arthritis the number of injections for the six who improved was 8, 17, 27, 37, 48, and 52 respectively, with an average of 31.5, while the four who failed to improve had 9, 13, 24, and 28 injections, with an average of 18.5. The duration of treatment for the former varied from two to 14 months and for the latter, from two to four months.

For the patients with a moderately severe arthritis the range of injections was from nine to 48 with an average of 21.5 for those who improved, while it varied from six to 25 with an average of 15.5 for those who did not respond. In the improved group half of the patients received 20 or more injections, while only two of the nine patients in the unimproved group

received as many. The duration of treatment for the former varied from one to 12 months, while for the latter it varied from one to four months.

For the patients with a mild arthritis and an elevated corrected sedimentation rate the number of injections for those who improved varied from six to 38 with an average of 18.7 and the duration of treatment from one to 10 months, while for those who failed to respond it ranged from eight to 26 injections with an average of 13.7 and a duration of from one and a half to three months. For the patients with a mild arthritis and a normal corrected sedimentation rate the average number of injections was 14.5 with an average duration of 3.2 months for the improved group and 15.9 injections over a period of 3.5 months for the unimproved group.

Very few untoward reactions occurred from the injections. One patient who was given a much larger dose than on the previous visit developed a severe urticaria immediately after the injection. It cleared up rapidly following an injection of adrenalin. One patient was given three wheals in the left forearm at the third visit. Two of the wheals disappeared in a few hours but one became inflamed and a cellulitis developed in the left hand and wrist two days later which required hospitalization and surgical intervention. Cultures from the site of injection were negative. The patient was found to have a history of recurring attacks of hay fever. Following the reaction the patient had complete relief from the arthritic condition and was well one year later.

DISCUSSION

The highest percentage of improvement occurred in the group of patients having a mild form of arthritis but with an elevated corrected sedimentation rate. However, the patients with the same form of arthritis but having a normal corrected sedimentation index did not respond well to treatment. This is probably due to the fact that many of the latter group were old or quiescent cases and some may not have had a true rheumatoid arthritis. This type of patient does not respond well to any of the usual forms of therapy.

As might be expected, improvement was directly related to the duration of treatment. The patients who improved had injections on an average of two to three months longer than those who failed to respond. Like most forms of therapy for rheumatoid arthritis it was necessary to continue the injections over a long period of time to get the best results.

In giving bee venom in the form of *Apicosan* care must be exercised in order to avoid reactions. The dose should be increased slowly and the patient should be questioned at the next visit regarding redness, pain and swelling at the site of the injection. The test dose (0.1 c.c. of concentration N) should always be given preliminary to starting the treatments as some people are very sensitive to bee venom.

It is of interest to compare the results obtained in this study with those following the use of vaccine. In 1933 Stainsby and Nicholls⁷ reported an improvement of 58.3 per cent in a group of 103 patients treated by the removal of diseased tonsils and injections of hemolytic streptococcus vaccine. One hundred and ninety-four patients in whom the focus of infection had been removed before coming to the clinic were treated with vaccine only and 35.9 per cent showed improvement.

SUMMARY

1 One hundred patients with rheumatoid arthritis were treated with an injectable form of bee venom (*Apicosan*) and 73 showed improvement. Thirty-five of the patients were markedly improved and 38 moderately improved. There was definite and lasting relief from the pain and swelling and a drop toward normal in the corrected sedimentation rate, if previously elevated.

2 The number of injections varied from 6 to 52 over a period of from one to 14 months. The patients who received on the average a longer course of treatment showed the greater improvement.

3 In estimating the results obtained from this study of an injectable form of bee venom (*Apicosan*) for rheumatoid arthritis one is impressed with the definite improvement in the clinical symptoms and the significant drop in the corrected sedimentation index in a large percentage of the patients. It would seem, therefore, that bee venom is worthy of further consideration.

MECHANISM OF THE TOXIC EFFECTS FROM COMBINED USE OF CALCIUM AND DIGITALIS *

By J S GOLDEN, M D , and WILLIAM A BRAMS, M D , *Chicago, Illinois*

THE administration of calcium with digitalis was considered a safe combination to enhance diuresis and to increase the effects of digitalis by Berhner,¹ Billigheimer² and Singer¹⁵. Recently, however, Bowers and Mengle⁴ reported sudden death in two patients who received calcium intravenously after previous administration of digitalis, and similar results were noted in animals that received a similar combination. Available experimental evidence points to either a synergistic effect or an additive phenomenon as the underlying factor for such untoward results. Lloyd¹ reported the electrocardiographic changes observed on himself during intravenous administration of calcium chloride, using first 50 c c of a 1 per cent solution and then a 10 per cent solution. No significant changes were observed during injection of the weaker solution but subsequent use of the 10 per cent solution resulted in cardiac standstill after but 4 c c had been given. Complete recovery followed when the injection was stopped at that point but this experience shows that intravenous injection of calcium is not always harmless. Walters and Bowler¹⁶ injected a 10 per cent solution of calcium chloride intravenously in dogs and found electrocardiographic evidence of changes in rate and conduction. Ventricular fibrillation was observed after toxic doses but therapeutic amounts resulted only in changes in heart rate. Billigheimer³ explains the change in rate as due to an effect on the vagus. Lieberman^{9,10} reported that intravenous injection of calcium produced effects closely resembling those produced by digitalis, namely, rise in blood pressure, slowing of the pulse, heart block, and various arrhythmias. This author^{10,11} believes that intravenous calcium produces an almost instantaneous digitalis-like effect on the heart while an interval of time is required for digitalis to act. He thinks that the result of both drugs given simultaneously or shortly after one another is merely additive. Billigheimer² thinks that calcium and digitalis act on the same structures of the heart but believes that digitalis sensitizes this organ to calcium. Similar observations were made by Mandelstamm¹³ and by Issekutz⁸. It is of interest to note that Edens and Huber⁶ found the blood calcium to be elevated when bigemini pulse appeared after digitalis and that Cushny⁵ reported less complete cardiac contractions after digitalis when the calcium content of the perfusion fluid in his preparations was reduced. Fischer,⁷ using isolated frogs' hearts, observed that calcium in the strength used in Ringer's solution, or in higher concentrations, had no effect if given before or during digitoxin administration but a marked calcium effect became apparent if

* Received for publication May 22, 1937

From the Cardiovascular Department, Michael Reese Hospital, Chicago, Ill

digitoxin was employed before the calcium. He thinks that digitoxin sensitizes the heart to calcium but points out that this synergistic effect is one-sided, being effective only if digitoxin is given first. Schuntermann¹⁴ found greatly increased amounts of calcium in portions of dried myocardium in instances of cardiac hypertrophy with failure.

These differences in opinion as to the safety of the combined use of calcium and digitalis prompted us to reexamine the question in order to study the various factors and underlying mechanisms which may be responsible for the untoward results or death following this procedure.

PROCEDURE

Eleven dogs, each 8 to 12.5 kilograms in weight and anesthetized with sodium barbital, were employed. Digalen* was administered intravenously to the animals at a constant rate and in doses from 50 to 90 per cent of the calculated lethal dose (1.12 cat units per kilogram). After an interval of from 30 to 54 minutes 10 or 20 per cent solution of calcium gluconate was injected in the vein in five of these dogs. The quantity of calcium gluconate used did not exceed 20 per cent of the approximate lethal dose in any instance and the rate of injection was 4 c.c. or less per minute. Five other dogs received similar quantities of the two drugs simultaneously from the same syringe. The same precautions as to rate of injection and quantity of calcium were observed. Blood pressure variations were noted throughout each experiment. Electrocardiographic studies were made which included a three-lead control and repeated tracings of Lead II after each injection as well as prior to the death of the animal.

DISCUSSION AND RESULTS

The results are summarized in tables 1 and 2. In table 1 are shown the experiments where calcium gluconate was given 30 to 54 minutes after the digalen. The results obtained when the calcium gluconate and digalen

TABLE I

| Experiment Number | Per Cent of Calculated Lethal Dose of Digalen | Calcium Gluconate | Time Interval | Result |
|-------------------|---|-------------------|---------------|----------------------------|
| 1 | 85 | 15 c.c. 10% | 30 min | Immediate death |
| 2 | 66 | 25 c.c. 10% | 36 min | Immediate death |
| 3 | 60 | 11 c.c. 20% | 54 min | Dog destroyed after 22 min |
| 4 | 50 | 35 c.c. 10% | 31 min | Death in 60 min |
| 5 | 50 | 35 c.c. 10% | 38 min | Death in 90 min |

* We are indebted for the supply of digalen to Dr. L. Klein of Hoffmann-LaRoche and to H. Althouse of Sandoz Chemical Works for the calcium gluconate employed in these experiments.

were given simultaneously are shown in table 2. It will be seen that death occurred in both types of experiment with less than the calculated lethal doses of digalen, indicating that the calcium gluconate was in some way responsible for the greater effectiveness of digalen. Neither the rate of injection of calcium, which was constant in all experiments, the concentration or the total dose, which was never more than 20 per cent of the calculated lethal dose, could be responsible for death in some of the animals. Death of the animals and the time lag of its occurrence were found to depend on (a) the amount of digalen given, and (b) on whether the calcium gluconate was given simultaneously or at a short interval after the digalen. Both tables show that death occurred earlier with larger doses of digalen. It was also observed that death occurred earlier and was more likely to be

TABLE II

| Experiment Number | Per Cent of Calculated Lethal Dose of Digalen | Calcium Gluconate | Time Interval | Result |

(1) 0 equivalent to simultaneous administration

(2) Dog 2 received a second dose of digalen (17 per cent of the calculated lethal dose) 28 minutes after the injection of calcium and showed no change for 28 minutes until another injection of calcium was given. Death then occurred in 2 minutes.

sudden with the same large dose of digalen if the calcium was injected about 30 minutes after the digalen. This, of course, is due to the time lag before the full action of digalen appears. In other words, in the simultaneous injections the calcium effect could have worn off considerably before the digitalis effect had become prominent. Nevertheless, it is significant that death sometimes occurred after a long interval when smaller doses of digalen were used. Apparently the effect of calcium gluconate may sometimes be more prolonged than is generally supposed.

The lag in death with smaller doses of digalen is in accord with some unreported results obtained by one of us (W. A. B.) with cats which indicated that intravenous injections of very large doses of digitalis resulted in toxic effects within a few minutes while comparatively small doses of digitalis required more time to produce comparable effects.

The present study indicates the hazard existing in the use of calcium gluconate intravenously following digitalis. Great caution should be used in patients who have received digitalis, especially if they show electrocardiographic or other evidence that they are digitalized. Even the simultaneous injection of calcium and digitalis in patients who have not previously received digitalis is not a harmless procedure. It is especially dangerous if larger doses of digitalis are given but untoward results may occur with smaller therapeutic doses. Our animal experiments suggest that the margin of safety in such combinations is both variable and narrow and that death may occur as late as one to one and one-half hours after injection.

Our experiments throw no light on whether death is due to additive phenomena or to a synergistic effect but it was observed that blood pressure rose shortly after injection of digalen in most instances to be followed by a precipitous drop before death after calcium was given. Electrocardiographic observations show the usual changes after large doses of digitalis, namely, changes in the T-wave and ST segment, heart block and ventricular tachycardia. Subsequent injection of calcium resulted in ventricular tachycardia and ventricular fibrillation. The latter mechanism was the cause of death in the animals who died immediately as well as in those who lived for as long as 90 minutes. Even those who survived developed ventricular tachycardia when digalen and calcium were injected simultaneously.

RÉSUMÉ

1 A series of experiments was performed to study the dangers and their mechanisms, inherent in administration of calcium with or shortly after digitalis.

2 We are in accord with previous observers who noted marked toxic effects or death when such combinations were used. These results could not be attributed to the digalen alone nor to the concentration, dose or rate of injection of the calcium.

3 The toxic or fatal effects depended on the size of the previous dose of digalen and depended a great deal on the time interval between injection of digalen and calcium. Toxic manifestations and death occurred when larger doses of digalen were used. These were more likely to occur if calcium was injected about 30 minutes after the digalen.

4 It was also observed that the margin of safety was narrow and uncertain and that the toxic effects following calcium, when digalen was given before, resembled those seen after very large doses of digitalis alone. Simultaneous injection of both drugs in similar dosage was somewhat less toxic and was less likely to be fatal than when an interval of about 30 minutes elapsed between the injection of digitalis and calcium.

5 Death in our animals was associated with a precipitous fall in blood pressure, and electrocardiograms revealed that ventricular tachycardia was frequent and that death was due to ventricular fibrillation.

6 The conclusion is reached that great caution is to be used in giving calcium intravenously with or shortly after digitalis. It is apparently not safe to use this combination even in patients who have received small doses of digitalis, but it is particularly dangerous if there is electrocardiographic or other evidence that the patient is approaching digitalization. We believe that it is wiser to abstain from intravenous injection of calcium in any patient who is receiving digitalis since the margin of safety is so narrow and the toxic effects can neither be foreseen nor successfully treated.

We are indebted to Messrs A C Meyer, Jr, and R Blake for technical assistance in these experiments.

GENERAL INCIDENCE OF RHEUMATIC DISEASES, SOCIAL AND ECONOMIC IMPORTANCE

STATISTICS again demonstrate that the rheumatic diseases represent one of the world's greatest social and economic problems. Of all patients admitted in 1933 to accredited hospitals in the United States, 97,984 patients (1.39 per cent) were admitted because of "arthritis or rheumatic diseases" (Kling³¹³). A recent Public Health Survey (Collins⁹⁶) calculated the incidence of "chronic arthritis and rheumatic diseases" as 22.18 per 1000 persons, or 2.2 per cent of the population of which more than 1 per cent had "disabling" rheumatism and 0.85 per cent were "bedridden." (The morbidity rate for tuberculosis of all forms, including suspected cases, was only 4.72 per 1000, about one-fifth that of chronic rheumatism.) Based on these figures, Kling calculated that about 2,700,000 of the 120,000,000 population in the United States are affected with chronic rheumatic diseases, of whom 1,230,000 are "disabled" and 1,020,000 have been bedridden at some time or other. (Presumably the remaining 450,000 persons were affected mildly or moderately, not seriously enough to be "disabled" or bedridden—Ed.) Kling believes this to be a low estimate. According to the Massachusetts survey (1933),²⁴⁵ 3,264,000 persons or 3.2 per cent of the population of the United States suffer from chronic rheumatism.

The incidence of joint diseases in Finland is evidently less. In a house-to-house canvass of 37 rural communities with a population of 195,000 persons, Holsti and Rantasalo found 1702 persons (0.9 per cent) who had suffered or were suffering with "acute or chronic joint disease", of these 1177 had chronic arthritis, 525 had acute arthritis. Sex incidence of those affected was 2.4 females to 1 male, in acute cases 1.7:1, in chronic cases 2.7:1. The incidence of arthritis in different localities varied greatly from 0.3 to 4.3 per cent of the population, and was highest in southeastern Finland, on the coast of Lake Laakokka, where endemic struma is common.

CLASSIFICATIONS OF DISEASES OF JOINTS AND RELATED STRUCTURES

The editors of these reviews^{245, 246, 247} sympathize with Haden when he stated, "It is hopeless to discuss the different classifications or the different terms used to indicate the same *clinical type of pathologic process*." In the third review we therefore dismissed the year's crop of "new classifica-

tions" briefly since none seemed subject to less criticism than those in common use. A commission of the International League against Rheumatism has already collected more than 60 different nomenclatures. The ultimate classification of "rheumatic diseases" will be one based on a complete understanding of the etiology of the different forms. Until an etiologic classification can be completed it is necessary to use working classifications based on clinical data, pathologic or roentgenographic features or combinations thereof. None is entirely satisfactory but some have more merit than others. Because of the fundamental differences of opinion among the various schools of thought it is difficult to set up a nomenclature universally acceptable. But to avoid clinical confusions and for statistical purposes an international classification would be most helpful. To foster such a classification the International League against Rheumatism has asked committees in each country to simplify its own nomenclature to bring out the essential features of each disease-type. Cooperating in this work, a committee appointed by the American Rheumatism Association is critically reviewing major classifications now in use. This review will therefore not include critical comments on new ones proposed. Those interested in suggestions, amendments and criticisms of classifications in current use may consult the following references 4, 14, 129, 177, 183, 191, 223, 286, 318, 428, 476

DISEASES OF JOINTS RELATED TO TRAUMA

Trauma is related to articular disease in three ways: it may be the chief or sole cause of "pure traumatic arthritis", it may precipitate various types of arthritis, chief cause of which is some factor other than trauma, it may aggravate a preexisting active or quiescent nontraumatic arthritis. Campbell regards traumatic arthritis as the commonest type of joint affection.

(This may be true in the practice of an industrial surgeon or orthopedist but is not the experience of most physicians unless one regards as traumatic arthritis all three of the relationships listed—Ed.)

Articular Diseases Due Primarily to Trauma Three types of trauma produce articular damage⁷⁶ (a) A single mild or severe injury which damages articular structures with varying degrees of severity, (b) repeated occupational trauma from overuse and excessive wear and tear of joints, (c) repeated "microtrauma" from faulty posture or attitudes producing functional disability from unevenly distributed intra-articular pressure.

Symptoms The usual symptoms of pure traumatic arthritis result from the reaction of synovial, capsular or articular tissues to the irritative process⁷⁶. Traumatic arthritis is usually monarticular, rarely bilateral or polyarticular. Pain and slight swelling are generally present. Periarticular skin temperature, often increased in infectious arthritis, is usually normal in traumatic arthritis. On motion, crepitus may be present from a thickened capsule, synovial villi, or irregular articular surfaces. The joint may appear normal or effusion may occur. Large effusions may force articular

structures to assume abnormal positions which provoke muscle spasm and limited motion

Pathology Chief lesions produced are cartilage degeneration and, less notably, synovial fibrosis. There is early splitting of the cartilage matrix and subsequent fibrillation which may result in complete destruction of the cartilage of weight-bearing surfaces or of cartilage covering those surfaces affected by trauma (Ghormley and Deacon). These changes result because cartilage has little reparative powers. Marginal osteophytes appear later. The development of these changes has been reviewed (Campbell, Kling). Synovial hydrops is followed by formation of fibrin which may become organized into fibrous tissue adhesions. Synovial villi may increase in size and number. Beneath the synovia a fibrous tissue reaction occurs. Disease of cartilage produces no pain as sensory nerves are absent. When significant intra-articular hemorrhage occurs the synovia responds by hypersecretion, becomes thickened and inflamed. Blood is broken down, fibrin is precipitated and becomes organized with formation of adhesions.

Roentgenogram In the early stage of traumatic arthritis roentgenograms may be normal or may reveal subchondral osteoporosis. Later the hypertrophic changes and osteophytes are seen.

Synovial Cytology and Chemistry Normal synovial fluid contains about 10 to 200 nucleated cells per cu mm, and, according to Collins, a small, variable number of erythrocytes, from the trauma of aspiration. Only an occasional polymorphonuclear leukocyte occurs among the nucleated cells, 90 to 95 per cent of which are phagocytic cells resembling either monocytes of blood or macrophages of probable connective tissue origin. Collins studied the cytology of five traumatic effusions between seven and 51 days after injury. Variations in total and differential cell counts were as follows: erythrocytes, 200 to 25,000 per cu mm; total nucleated cells, 150 to 856 per cu mm; polymorphonuclears 2 to 32 per cent, lymphocytes 34 to 77 per cent, monocytes 9 to 18 per cent, macrophages 0 to 8 per cent, synovial cells 3 to 38 per cent.

In hemorrhagic traumatic effusions Kling found an increase of mucin, the presence of which increases the viscosity of the effusion. As a result of hemorrhage, the bilirubin content of the effusions may be increased for as long as six weeks after an injury. The icteric index of traumatic effusions is above 5, that of inflammatory effusions is invariably below 5. Other than trauma, only a few conditions (hemophilia, tabetic atrophy, xanthoma, sarcoma) cause spontaneous intra-articular bleeding and a high bilirubin content in effusions. The presence of fat in traumatic effusions distinguishes severe injuries from simple tears of joint capsule. If the fat is chiefly palmitin and stearin, it presumably originates from fat torn loose from fat pads and may indicate an injury to the intra-articular cartilages or to ligaments. If it is chiefly olein it must come from bone marrow, therefore its presence indicates intra-articular fracture. In such cases bone marrow cells may also be present in effusions.

SPECIAL FEATURES AND VARIETIES OF TRAUMATIC DISEASE OF JOINTS

1 "*Post-Traumatic Bone Atrophy*", "*Post-Traumatic Periarticular Fibrosis*" In 1900 Sudeck described an "acute post-traumatic inflammatory atrophy of bone" Since then considerable attention has been paid to the osteoporosis, but little to the associated periarticular fibrosis The cause of this osteoporosis is unknown but is presumably the result of a physiologic process which follows every toxic or traumatic irritation and is probably the result of an increased circulation to the part from vasomotor alterations initiated by the sympathetic nervous system Absorption of bone salts appears in roentgenograms as a "spotty atrophy" or mottling⁷⁶ It is differentiated from the atrophy of disuse, which is characterized by gradual encroachment of the marrow on the cortex and by diminution in the size of the entire bone

Post-traumatic bone atrophy may be painful In one case Ghormley noted atrophy of cartilage Gordon regarded the bone atrophy as secondary to the earlier periarticular fibrosis Following an injury or fracture of an extremity, swelling and a soft pitting edema distal to the lesion may appear and persist Joints of hands or feet may become painful and stiff due to proliferation of periarticular fibrous connective tissue Subsequent decalcification of bone occurs Lymph stasis supervenes, later the vascular content of subcutaneous tissues is apparently reduced Overgrowth of periarticular connective tissues occurs, limitation of motion and pain are present, contractures and protective muscle spasms ensue, and atrophy results In severe cases roentgenograms show decalcification of bone, slight thickening of periarticular tissues, narrowing of joint spaces If the original injury or fracture is near the torso, this condition is less likely to affect hands and feet because collateral circulation of blood and lymph distal to the original injury is generally adequate

The condition is avoided by preventing or correcting capillary and lymph stasis Only that part of the extremity for which rest is vital should be kept at rest Rings should be removed Dressings should not be constrictive Adequate, protective cotton pads should be used with splints and the latter should be temporarily removed to permit massage if swelling appears Frequent elevation of affected extremities is important Usually the condition clears satisfactorily, occasionally it is protracted In severe cases one or two toes or fingers may become ankylosed Relief was obtained in two cases treated by White with procaine injections of sympathetic ganglions

Apropos of these statements is Jones' interesting review of the conditions which foster articular adhesions with injury or disease

The following questions were raised and answered by Jones Why may joints sometimes be immobilized without becoming stiff, whereas at other times dense adhesions form although joints have not been completely immobilized? Why can some joints be immobilized for a year with impunity, and others become permanently stiff within a few weeks? Why is the wrist joint more likely to become stiff when immobilized in a cock-up splint and not in a dorsal plaster splint? Why do massage

1094 HENCH, BAUER, GHRIST, HALL, HOLBROOK, KEY AND SLOCUMB

and passive stretching always aggravate stiffness of finger and elbow joints? Joint adhesions from injury are generally formed, not in intra-articular or interarticular, but in periarticular, tissues. Stiffness results from periarticular adhesions in the plications of joint capsule. Adhesions arise from organization of periarticular sero-fibrinous exudate which provides the adhesive substance responsible for the gumming together of adjacent tissues. First a fibrinous deposit occurs, later fibrin is replaced by young connective tissue, ultimately by fully formed fibrous tissue. When traumatic (or infectious) synovitis occurs, or when the joint capsule is torn, exudate is poured out from synovia or from torn edges of the capsule. Even though the joint is normal, periarticular adhesions may form as a result of certain extra-articular conditions: a spreading exudate from distant injury or infection, recurrent edema of juxta-articular tissues, simple venous stasis and congestion due to muscular inactivity of immobility and disuse. The potency of these factors in promoting adhesion formation depends on the degree of exudation, the fibrin content of the exudate and the frequency with which the soaking is repeated. The recurrence and persistence of serofibrinous exudation provide the key to adhesion formation. If articular tissues are soaked in exudate, day by day, adhesions will form whether immobility is complete or incomplete and whether the joint is injured or normal. If injury is not repeated, even a severe fracture of an elbow joint will cause less adhesion formation than the relatively trivial injury of passive stretching repeated day after day by an overenthusiastic masseur. Adhesions form less readily about an ankle joint immobilized in a walking plaster cast than about the same joint left free to move but subject to recurrent edema. "Edema is the glue from which adhesions are made" (Not ordinary edema, but that from inflammation and trauma—Ed.)

2 *Pellegrini-Stieda Syndrome* When the medial collateral tibial ligament of a knee is traumatized a peculiar reaction may occur therein: bone may be formed in the ligament. This is the Pellegrini-Stieda syndrome, recently described in American literature (Kulowski, 1933). Two cases were reported (Henson). Each involved a history of recurrent trauma, swelling of the knee and pain on motion. Roentgenograms revealed the condition. Surgical procedures used in treatment were outlined.

3 *Tennis-Elbow* There is no unanimity of opinion concerning the basic pathology or the optimal treatment of "tennis-elbow." According to Cyriax, it is caused primarily by a tear between the tendinous origin of the *extensor carpi radialis brevis* and the periosteum on the anterior surface of the lateral epicondyle, a chronic periostitis results secondarily and to this symptoms are referable. Cyriax described his method of treatment which gave "complete and lasting relief": repeated deep friction to the tender area, followed by forced adduction of the extended and supinated forearm.

Medicolegal Aspects of Traumatic Arthritis Data considered necessary by some to determine the presence of traumatic arthritis and to assess the degree of disability therefrom have been given^{245, 247}. It was stated that, in addition to other data, one should have information on the time between injury and onset of symptoms, it should not be more than a few months to a year. Some disagree on this last point. According to Henry the injury must be severe enough to cause immediate cessation from work and symptoms must appear immediately (or within a few days) after the accident and persist continuously. According to Lecklitner "bridge symptoms"

must be present, that is, the symptoms (to be caused by traumatic arthritis) must have continued uninterruptedly from the time of trauma to the onset of arthritis, and other joints of the body must be free of arthritic lesions

Nontraumatic Arthritis Precipitated by Trauma Mild trauma may instigate or precipitate an arthritis (atrophic or tuberculous, or that from syphilis, pyogenic infections or neoplasms) the chief cause of which is some factor other than trauma In a gouty patient mild trauma may initiate a severe attack of gouty arthritis, out of all proportion to the degree of trauma which provoked it (Campbell, Kling)

Nontraumatic Arthritis Aggravated by Trauma Any preexisting arthritis (most commonly hypertrophic, senescent or degenerative osteoarthritis) may be aggravated by trauma In patients with previously asymptomatic, senescent hypertrophic arthritis trauma may induce persistent symptoms In such cases the medicolegal question arises how much disability is attributable to trauma and how much to the previously existing disease? ⁷⁶

In three patients Epstein noted results of severe trauma to joints ankylosed from previous disease Fracture occurred not at the site of ankylosis but in adjacent, thinner para-articular bone Hence a completely welded, eburnated articulation of two long bones of an extremity, that is, a true ankylosis, is a mass of bone of greater strength than that of nearby "healthy" bone

TREATMENT OF TRAUMATIC ARTHRITIS

Current treatments are as previously outlined in the first three reviews Aspiration of traumatic effusion evacuates pathologic products from joint cavities and reduces inflammation (Kling) Henson inflated joint cavities with oxygen to prevent and to "break up" post-traumatic adhesions (also those from infection) Weight bearing and physiotherapy were used in addition to oxygen inflations Motion of joints was restored more readily and more painlessly by this combination than otherwise Pain was generally decreased and manipulation of joints avoided

Histamine ionization was advocated (Mackenna) Short wave therapy was used by Speeding

(Evidence proving the superiority of these measures was almost wholly lacking in these reports—Ed)

"GONORRHEAL RHEUMATISM" GONORRHEAL ARTHRITIS

Incidence In the United States 700,000 persons apply annually for the treatment of acute gonorrhea (Barney) According to Usilton (1935) about 500,000 patients in the United States are constantly under treatment or observation for gonorrhea Considering those with gonorrhea who never report for treatment it has been estimated that between 1,000,000 and

2,000,000 new infections with gonorrhea occur yearly in this country (Thomas and Bayne-Jones, Barney) About 3 to 5 per cent of persons with gonorrhea are said to develop gonorrheal arthritis of varying severity A much lower incidence is reported from Johannesburg, South Africa of 6000 patients with gonorrhea, 30 (0.5 per cent) developed gonorrheal rheumatism (Bayer)

Clinical Features Reviewing the clinical features of gonorrheal arthritis Warren stressed certain points A careful history usually reveals transitory involvement of many joints for several days at the onset, then the acute major involvement, generally of one but not infrequently of several joints or near-by structures Often the process subsides in one joint and flares up successively in other joints, particularly in a previously traumatized joint In some cases the process is restricted entirely to tendon sheaths or bursae around a joint or to nearby muscles and fascia A notable feature is the rapidity with which the acute arthritis and bone and muscle atrophy progress

Gonorrheal arthritis in children is rare In one series of cases it occurred in 1.5 per cent of children with gonorrheal vulvovaginitis (Gittings and Mitchell, 1917) Su and Hu noted severe gonorrheal polyarthritis in a girl aged four years who had apparently contracted the disease from recently infected parents The child developed vulvovaginitis, fever, adenopathy and arthritis in three joints Although treatment was chiefly symptomatic, articular recovery was complete

(It often is if organisms do not invade the articular cavity—Ed.)

The simultaneous occurrence of gonorrheal arthritis in a mother and a newborn infant is rare, an instance is reported by MacLennan Infants with gonorrheal ophthalmia may develop arthritis between the fifth day and the fifth week, generally the second week, of infection Although infants with severe ophthalmia may die, prognosis regarding joints is usually good

Most cases of persistent gonococcemia are fatal Among the 27 cases of nonfatal gonococcal septicemia without endocarditis reported in the literature two patients had erythema nodosum An additional case was reported by Bakst, Foley and Lamb

Pathology The "classical type" of reaction occurs when articular tissues are directly invaded by gonococci There is an inflammatory synovial reaction with infiltration of leukocytes, lymphocytes and macrophages In synovial exudates are found gonococci and inflammatory cells, especially leukocytes Jordan regarded as unproved the existence of a "second type" of gonorrheal arthritis in which gonococci are not found in articular and peri-articular tissues to explain the inflammation therein Some suppose that such a type represents an "allergic gonorrheal arthritis," a sensitization of joint tissues to metabolic products of distant gonococci According to Ghormley and Deacon, the pathologic reaction in gonorrheal arthritis is essentially similar to that of other pyogenic forms of arthritis synovial

thickening, edema, polymorphonuclear leukocytic infiltration, later the production of fibroblasts and capillaries, infiltration by plasma cells and polymorphonuclear leukocytes, and still later the advanced stage of synovial fibrosis. Differences in reaction depend largely on the number and virulence of the organism and the patient's resistance.

Roentgenograms In acute gonorrheal arthritis roentgenograms present no special characteristic except perhaps the early and unusual, diffuse character of the atrophy and the marked, often rapid, bone destruction (Warren). Taylor and his colleagues regarded this feature as of considerable diagnostic value to clinicians. The appearance of a gonorrheal joint of six weeks' duration may closely resemble the appearance of a joint with tuberculous involvement of six months' duration. To suggest a diagnosis of gonorrheal arthritis, therefore, a roentgenologist should know at least the duration and severity of articular symptoms. Studying roentgenograms in 11 cases, Taylor and associates noted marked variations at different stages of the disease. In the "early stage" marked soft tissue swelling appeared early and subsided within a few days or weeks. Local areas of decalcification and slight effusion were each noted in 64 per cent of these cases. Later these both decreased. Later still there was narrowing of joint spaces in 82 per cent, a moderate degree of "active bone destruction" in 36 per cent, early healing with fibrous or bony ankylosis in 45 per cent.

Laboratory Data A certified diagnosis of gonorrheal arthritis can be made only on recovery of gonococci from articular tissues or fluid. This is generally not done. A reasonably accurate presumptive diagnosis of gonorrheal arthritis is usually made on the basis of certain clinical data supported by laboratory evidence of the presence of urogenital gonorrhea. The elaborate report by Thomas and Bayne-Jones of the Committee for a Survey of Research on the Gonococcus and Gonococcal Infections contained much data of interest to clinicians: data on the biology of gonococci, on types of gonococcal infections, on the relative value of different methods of treatment of gonorrhea and on the respective merits of laboratory tests used in diagnosis.

1 Isolation of Gonococci in Smears and Cultures Although in most cases of acute gonorrhea in males a diagnosis based on examinations of stained smears from secretions is probably correct, such a diagnosis is not free from uncertainty. Recent literature reflects a growing sentiment against relying on smears alone for diagnosis (Thomas and Bayne-Jones). Although opinions differ as to the relative value of smears or cultures for isolating gonococci, most workers now favor cultures. Warren's experience indicated that smears from urogenital discharges may be positive for gonococci in 40 per cent, cultures of such discharges may be positive in 60 per cent, and cultures of articular tissues may be positive in 80 per cent of cases in which gonorrhea is suspected. These percentages are higher than those of others. Leahy and Carpenter found the diagnostic value of smears slightly greater than that of older cultural methods but when they used a modification of McLeod's new (1928-1934) method the reverse was true. Ten per cent more positive cases of gonococcal infections were discovered by the new cultural method than by the smear method alone. Smears were positive in 45 per cent, cultures positive in 55 per cent of cases studied, in 13 per cent cultures were positive when smears were negative or doubtful, in 2

per cent cultures were negative but smears were positive. Similar results were obtained by Spohr and Landy, using another modification of McLeod's method. A study of material from male urethras gave the following results. Smears and cultures were both negative in 22 per cent of cases examined, smears were negative but cultures were positive in 10.3 per cent, smears were positive but cultures were negative in 7.7 per cent, both smears and cultures were positive in 60 per cent. The superiority of the cultural method was more notable in tests on material from suspected females. In studies of urethral secretions smears and cultures were both negative in 52.5 per cent, smears were negative but cultures were positive in 10.2 per cent, in no case were smears positive and cultures negative, in 37.3 per cent both smears and cultures were positive. Studies of cervical secretions revealed negative smears and cultures in 49.2 per cent, negative smears and positive cultures in 3.2 per cent, positive smears and negative cultures in none, positive smears and cultures in 18.6 per cent. Thus, in the latter group smears were positive in 18.6 per cent but cultures were positive in 50.8 per cent.

2 Gonococcal Complement-Fixation Test Further experiences with this test indicated that, properly interpreted, it is of diagnostic value. For the test to be positive, enough antigen must be absorbed to stimulate the formation of sufficient antibodies to produce the reaction in blood and a period of time sufficient for the development of the reaction must have elapsed. In mild or 'subacute' (as contrasted with acute) cases, or in those in which discharges are open and draining freely, and in which but little antigen is absorbed, the test may remain negative despite the presence of definite gonorrhea. The current reports of Warren, Pelouze, McEwen, Alexander and Bunim, Hirshland and Hirshland and Lin have restated the characteristics of the test. 1 The test may be negative the first two to six weeks of infection. 2 It may require 4 to 20 weeks for complete fixation to occur. 3 Tests should be repeated, especially if the first ones are negative. A positive test was frequently not obtained by McEwen and associates until the third bleeding. 4 Some²⁶⁵ regard a repeatedly weak-positive reaction as specific as a (single) strongly positive reaction (Others do not agree to this—Ed). 5 The test is more frequently positive in acute systemic infections (such as gonorrheal arthritis) or in chronic infections than in acute local infections. 6 Repeatedly negative tests are strong presumptive evidence against the presence of gonorrhea. 7 After patients have clinically recovered the test may remain positive for many months (as long as four years—Warren), therefore it is of little value as an immediate proof of cure. 8 The test generally becomes negative within 6 to 18 months after clinical recovery. 9 A persistently and markedly positive reaction in a case of presumed arrested gonorrhea strongly suggests the presence of a (hidden) active gonococcal focus³⁴⁴.

Results of the test confirmed the clinical diagnosis in 76.4 per cent of the cases of Hirshland and Hirshland who found it particularly useful in females from whom it is difficult to obtain positive pelvic smears. Of 44 patients with gonorrheal arthritis seen by McEwen, Alexander and Bunim, 98 per cent gave a positive reaction. 4 plus in 20 per cent, 3 plus in 33 per cent, 2 plus in 36 per cent, 1 plus in 2 per cent, doubtfully positive in 7 per cent. False positive reactions were found in no normal controls but in several pathologic controls: in 2 per cent of 48 cases of osteoarthritis, in 3 per cent of 39 cases of atrophic, in 3 per cent of 36 cases of miscellaneous arthritides, in 7 per cent of 70 cases of rheumatic fever. Some of the latter patients had rheumatic polyarthritis and coincidental urogenital gonorrhea.

Lin tested the sera of 500 persons, 323 with active or arrested gonorrhea and 177 with nongonococcal infections used as controls. Of the control cases 3 per cent gave false-positive reactions. The reaction was falsely negative in 25 per cent of the cases of gonorrhea proved active by smears. Of 187 specimens representing cases of active gonorrhea, smears and serologic reactions were both positive in 95 cases, smears alone were positive in 31 cases, the serologic reactions alone were

positive in 33 cases. Complement-fixation tests generally became negative in less than 6 months after patients were clinically cured.

According to Thomas and Bayne-Jones the present status of the test is as follows. In spite of technical improvements it still remains one which cannot be satisfactorily done by a poorly trained or indifferent technician, and is one which exhibits, even when skillfully performed, vagaries whose conquest will demand time and research. Variations of materials and procedures used for the test have been so numerous that they defy classification. Various antigens, solutions, autolysates and protein-fractions of the organism are used. A greater standardization of technic is necessary and the most reliable antigen must be found. Despite all this the weight of evidence conclusively shows the specificity and considerable diagnostic value of the reaction.

Koopman and Falker devised a "more sensitive and quantitative" method for the test, one which does not give false-positive or indefinite reactions except in cases of meningitis. (No results with the test were tabulated—Ed.)

3 Skin Tests Although some workers regard skin tests with various products of gonococci as of diagnostic value, there is no general agreement on their worth.⁵⁴³ Conrad used the Corbus-Ferry filtrate and a control solution for skin tests on 50 cases with no history of gonorrhea, and on 50 cases with clinical and laboratory evidence of gonorrhea. Forty-eight hours after injection, 98 per cent of the 50 gonorrheal cases demonstrated a skin reaction averaging 2.3 cm. as compared to reactions averaging 0.2 cm. in the control cases. No false-positive or negative reactions were noted. According to Corbus, the mechanism of skin reactions to the Corbus-Ferry filtrate is due to allergy.

4 Synovial Cytology The cytology of 5 specimens of synovial fluid in 2 cases of gonorrheal arthritis of "considerable chronicity" was noted by Collins. Total nucleated cells varied between 5,200 and 23,400 per cu. mm., polymorphonuclear leukocytes, between 30 and 77 per cent.

Treatment This includes the management of the primary focus, that of the infected joints, and general treatment. Although fever therapy is being more widely used to heal both the local genital and articular disease, older methods are used by many. Stressed were the importance of early treatment even in mild cases, bodily rest to prevent systemic invasion, strict avoidance of trauma to genital tissues from the over strenuous use of instruments, massage and strong chemicals, avoidance of sexual and alcoholic stimulation, and the choice of various urinary sedatives and urethral medicaments.^{26, 30, 169, 402, 429, 543}

Local applications of different chemicals and the use of vaccines found little favor with Thomas and Bayne-Jones. When chemicals are strong enough to affect bacteria they generally irritate tissues. Most specialists in the United States question the usefulness of vaccines except perhaps in chronic or complicated cases. The manifold preparations made from gonococci and used as vaccines "indicate that none fulfills all requirements. After all in the present state of knowledge concerning the clinical composition of the organism and its metabolic products preparing them is like shooting in the dark."⁵⁴³ Several, however, favored the use of Corbus-Ferry filtrate. With it James "cured" 20 of 34 cases and Jamieson "cured" all of 9 cases of acute or chronic gonorrhea.

(Data on controls were not given—Ed.)

Corbus believed that the filtrate prevented complications, they occurred in only 3 per cent of 175 cases, arthritis never developed. In cases treated otherwise, when arthritis appeared it frequently yielded "completely in an exceedingly short time" with the use of filtrate and prostatic massage.

Others consider the filtrate valueless. The results of McKenna, Goldfader and Fishberg in the treatment of 34 cases of gonorrhea with routine treatment plus the filtrate were no better than those treated only routinely. Complications were not prevented. Spence obtained "uniformly poor results." Miller's³⁶⁷ results with filtrate were "not remarkably better" than those obtained otherwise. Deakin's patients with acute gonorrhea did not do so well with the filtrate as without.

Bertoloty and Herraiz considered Loeser's (1930) method of producing active immunization by injections of live gonococci superior to classical vaccine therapy.

The treatment of the joints includes rest with the appropriate type and amount of immobilization, physiotherapy and analgesics. According to Hamilton, amiodoxyl (ammonium o-iodoxybenzoate) has a profound effect on the pains of gonorrheal arthritis although it is useless in atrophic or hypertrophic arthritis. He compared results in 38 patients with gonorrheal arthritis treated therewith to those in 30 patients treated with ordinary methods. Amiodoxyl relieved pain, shortened the period of disability and reduced the percentage of permanent disability more effectively than any other generally used treatment. Of those treated with amiodoxyl, 69 per cent were "cured," 18 per cent improved, 13 per cent unimproved. Of the control group only 7 per cent were cured, 37 per cent were improved and 56 per cent unimproved. (Results in the controls were worse than usually reported—Ed.) The drug, given intravenously, may produce toxic manifestations, fever, erythema, vomiting, diarrhea, headache, when these occur its use should be promptly and finally discontinued or there may be a fatal result. Death occurred in one of Hamilton's cases and in five others noted in the literature.

(The reader cannot form an independent opinion from Hamilton's papers. Only meager details of his cases were given. His charts were difficult to interpret. The control group was apparently not comparable to that treated with the drug, 20 of the 30 control cases were of chronic, only 10 were of acute, arthritis. The analysis of the control group was "very incomplete because of lack of chart data." The value of the drug remains to be proved. It must be remembered that many cases of "gonorrheal arthritis" represent a transient polyarthralgia and disappear spontaneously—Ed.)

Gold therapy was used by Slot and by Oren.

Aspiration, drainage and irrigation of joints were advised in severe cases.^{231, 238, 297} Aspiration may relieve pain, protect intra-articular tissues from material which would destroy cartilage, prevent undue capsular stretching and reduce the formation of adhesions. If a large joint is involved and aspiration of synovial fluid reveals much fibrin, marked synovial leuko-

cytosis (more than 40,000 leukocytes per cu mm) and gonococci, Keefer favors irrigation through a small incision in the capsule. Burman devised an aspirating syringe with a side-cock adapter for injecting air into gonorrheal (and other) joints with effusion. Restorative treatment for joints includes the use of physiotherapy, protection of arches weakened by long rest, and procedures to correct flexion deformities or ankylosis.

For general debility blood transfusions and a liberal food intake were advised.²⁹⁷

Fever Therapy None of those advocating the measures just described apparently used fever therapy or compared its results with those of other methods. The parade of experience with fever therapy has continued to provide further evidence of its superiority over other methods.

Bierman and Levenson noted further results of systemic heating plus additional focal heating. The patients' temperatures were first elevated by means of a hot bath and cradle of lights to about 105° F (rectal). Then the pelvic temperature was further elevated to about 111° F by pelvic (rectal or vaginal) diathermy electrodes. Sixteen patients with gonorrheal arthritis were given two to six fever treatments, each three to five hours in duration, about twice weekly. The previous duration of gonorrhea was 4 to 28 (av 12.8) weeks, of the arthritis, 3 to 25 (av 10.2) weeks. Most of the patients had previously been treated ineffectively by other measures. Two already had ankylosis. Complete restitution of articular function was obtained in 13 of the 16 patients, partial restoration in one and very little in the two with ankylosis. Bierman also reported excellent results in the treatment of 52 cases of gonorrhea in females, in 26 of which salpingitis was present. In 45 of the 52 cases the cervix and urethra were sterilized after an average of 2.4 treatments per patient, 15 of the 45 patients required only one treatment.

Stecher and Solomon considered fever therapy practical, safe and satisfactory in the hands of experienced attendants. It provided cure or marked relief in a high percentage of cases and saved much time from disability. Fifty cases of gonorrheal arthritis were treated in the Kettering hypertherm, generally at 107° F for five hours⁵¹⁶; 54 per cent were "relieved of all joint symptoms," 22 per cent were benefited and 26 per cent were not helped. Of the 50 cases, 41 were of acute arthritis (10 weeks' duration or less), nine were of chronic arthritis. Complicating conjunctivitis and uinitis were promptly cured. Genital infections were generally but not always entirely cured.

Slaughter and Trautman, and Trautman with a Kettering hypertherm treated 25 patients with acute gonorrheal arthritis. 16 "recovered completely," five improved markedly, four moderately. Fifteen patients with chronic gonorrheal arthritis were also treated: ten recovered completely, three were markedly improved and two were not improved. Genital infections were cured concurrently in 22 of the 25 acute cases, in 14 of the 15 chronic cases.

Twenty-nine of Simpson's 31 patients with acute arthritis (of less than eight weeks' duration) and seven of 14 patients with chronic arthritis recovered "complete joint function" Marked articular stiffness persisted in two chronic cases in spite of fever therapy but was relieved by orthopedic manipulation under anesthesia followed at once by fever therapy Urogenital infections were completely cured in 38 of the 45 cases, soon disappeared spontaneously in four others, but two patients who had insufficient fever needed additional treatment

Of McClure's 16 patients with acute or chronic gonorrheal arthritis, nine were "cured," four improved, three stopped treatment prematurely "In some instances there was complete or almost complete relief from symptoms following the first treatment and from the experiences with these patients it is very definitely felt that fever therapy alone is often sufficient to effect a complete cure" For chronic cases supplementary physiotherapy was advised

Using a "hot box" alone Gurnee cured only 55 per cent of his cases of gonorrhea in females Treatments were strenuous and unsatisfactory Thereafter patients were treated in the "hot box" with additional pelvic heating by the Elliott method, oral temperatures being kept at 105° F, the water in the vaginal bag was at 115 to 118° F Thus, higher rectal temperatures were obtained in the presence of moderate cerebral temperatures and heat stroke was avoided All of five cases of gonorrheal arthritis were improved 90 to 95 per cent Their hospitalization was reduced 75 per cent of that necessary by older methods The combination of Elliott and "hot box" treatments seemed safer than that of Elliott treatments plus short wave diathermy, which Gurnee also tried

Fourteen of Owen's 22 patients with gonorrheal arthritis were "cured" by an average of 4.8 periods of fever of 4.6 hours each Eight patients who only averaged 2.8 periods of five hours each were improved, not cured, failures were due to insufficient heating "Given patients who can and will take the treatment, better than 80 per cent of gonococcic infections regardless of complications may be absolutely cured in the space of two weeks

This progress in therapy is most appreciated as it applies to arthritis, formerly so painful, time consuming and often permanently disabling" Ability to take treatments depended on the condition of the heart, the resistance of the skin to heating and the patient's temperament For one reason or another 12 per cent of Owen's patients were unsuitable for fever therapy

A summary of published results from the treatment of 151 cases of acute gonorrheal arthritis and 32 of chronic arthritis was made by Hensch

(This also appeared in the third review—Ed)

General Remarks on Fever Therapy The institution of fever therapy is not a simple matter to be done in a physician's office by a physician or nurse not specially trained in the technic It is a highly technical procedure which demands as much care as that required for a surgical operation

Even in the hands of a well trained personnel complications will occasionally occur, generally they are mild, but sometimes they are serious. Several papers included details on the management of patients under treatment, the contraindications, physiologic effects and complications^{12, 39, 41, 140, 141, 198, 219, 317, 385, 400, 418, 492, 510, 524, 541, 550}. The whole subject was extensively discussed in Neymann's review of 332 reports. Other reports noted the beneficial effect of fever therapy in gonorrhea uncomplicated by arthritis^{131, 140, 141, 362, 400, 494, 524}.

Contraindications to fever therapy were listed: advanced age, cardiovascular or renal dysfunction, chronic alcoholism, pulmonary tuberculosis, marked debility or emotional instability^{140, 141, 418, 524}. The hazards of fever therapy must not be overlooked. Certain patients are brought to the borderline of disaster by degrees of fever not tolerated by them. For details concerning the hazards, complications and accidents incident to fever therapy reference should be made to the reports cited. As Trautman stated, gonorrhea is not a mild disease, it can cause great disability, suffering and economic loss. Therefore the use of fever therapy is justified in spite of occasional failures or disasters. Trautman had experienced no fatalities in the treatment of 238 patients with 1383 fever sessions. Simpson noted no serious complications from 3204 fever sessions given to 431 patients.

(Warren, Scott and Carpenter noted one death in the treatment of 283 cases of gonorrhea in six years. At The Mayo Clinic one death occurred in connection with about 4500 fever sessions given to about 600 patients—Ed.)

Complications of fever therapy include first degree burns and cutaneous vesicles, diffuse erythema, occasional constipation, diarrhea, anorexia, nausea, headache, herpes labialis, dehydration and exhaustion, tetany, circulatory failure and heat stroke from loss of chlorides and cerebral hyperthermia. One of Stecher and Solomon's patients developed a severe, and two a mild, epileptiform seizure. When Gurnee used the "hot box" alone one of his 27 patients died of heat stroke and two developed severe heat stroke, but no serious effects were noted among his 30 patients treated by combined relatively low general and high pelvic temperatures.

(Details of the instance in which the patient died were not given—Ed.)

One of Stein's patients with gonorrheal arthritis responded well to two fever sessions, but about 12 days later signs of pyramidal tract involvement were noted which disappeared in two weeks. Three hundred thirty-one episodes of delirium were suffered by 108 of the 200 patients of Barnacle, Ewalt and Ebaugh who had a total of 1324 fever sessions. 204 of the episodes were mild, 118 moderate and nine severe. Delirium averaged 75 minutes (max 48 hours) and generally occurred in the first fever session. Large, but not small, doses of sedative drugs seemed to predispose thereto.

Additional reports of interest were of the following: electrocardiographic

changes in artificial fever⁵⁵⁴, velocity of blood flow in artificial fever^{318, 319}, effects of fever therapy on blood count, blood and urine chemistry^{118, 190}, temperatures of superficial and deeper tissues during hyperpyrexia⁴⁶³, the relative efficiency of various methods for producing fever^{244, 327}, a "satisfactory cheap device" for fever production¹³. The Therma-mode blanket was deemed not acceptable for use in fever therapy (Council on Physical Therapy of the American Medical Association)

Criteria of Cure of Gonorrhea These included the following disappearance of clinical signs of disease and of discharges, presence of clear urine without shreds, absence of gonococci in the shreds when these latter are present, two or three negative smears and cultures, presence of a prostate of normal consistency, prostatic secretion free from leukocytes, absence of urethral flare-up after sexual excitement or after alcohol, in women the presence of no visible cervical irritation, no tubal thickening or tenderness, no flare-up after menses (Brodie, Owens, Pelouze)

Prognosis, End-Results Spontaneous remissions of gonorrheal arthritis may occur with little residual damage "in a fair percentage of cases" (Warren). Certain patients even with gonococcemia may recover under symptomatic treatment alone (Su and Hu, Bakst, Foley and Lamb). However, the chances of residual articular damage are too great to neglect thorough treatment. Kuhns regarded the course of chronic gonorrheal arthritis (untreated by fever therapy) little different from that of other types of chronic arthritis.

(Many believe the term "chronic gonorrheal arthritis" should be restricted to indicate the past history and not to imply a forecast of progressive disease. The term should be used only to indicate that articular symptoms have already existed six weeks or more but not to signify that there is present a chronic progressive arthritis with prolonged symptoms of active inflammation. Gonorrhea rarely (if ever) produces chronic articular disease which progresses independently unless repeated infection or chronic trauma occurs—Ed.)

TUBERCULOUS ARTHRITIS

Clinical Data Current reports include several useful reviews. According to Henderson, the disease is less frequent because of better control of the milk supply and the education of the public on prevention and treatment. Nevertheless, Dickson stated that tuberculous arthritis is responsible for about 20 per cent of all the cripples in the United States. (The basis of this estimate was not given. It seems much too high—Ed.)

Dickson distinguished between tuberculous monoarthritis (the usual variety), multi-articular tuberculosis (tuberculosis may affect three or more joints in about 5 per cent of cases) and tuberculous polyarthritis or "tuberculous rheumatism" (which will be discussed separately). Tuberculous arthritis can be divided into two stages. 1. The early synovial or pseudosynovial, "preroentgenographic" stage, when the disease is roentgenographically invisible and no osseous foci are obvious, 2. A later stage when more or less definite roentgenographic changes are present.

Early symptoms include Generally an insidious onset, slight swelling or pain or both, sometimes merely stiffness, local warmth, a limp if the joint bears weight Constitutional symptoms may be absent or slight loss of weight, a little fever As the disease progresses the cartilage becomes eroded, the bone is exposed, pain and stiffness increase and affected children give night cries or there is jerking, especially in hips and knees, from contact of affected bone ends when muscles relax With progressive bone destruction abscesses may form with or without fever, depending on the occurrence of secondary pyogenic infection If synovia alone is affected, as occurred in 9 per cent of Henderson's cases, symptoms are chiefly stiffness and swelling If bone is primarily affected, as is usual, symptoms depend on the situation and size of abscesses They may exist for years, causing little discomfort If they break through into the joint abruptly, acute "panarthritis"—involvement of all structures of the affected joint—results Usually abscesses break through gradually and barriers of protecting adhesions are built up at the site

In Dickson's 158 cases of tuberculous arthritis, joints involved were as follows spine in 62, hip in 41, knee in 25, ankle in 11, wrist in 10, sacro-iliac in 6, shoulder in 2 and elbow in 1 case

Multiple arthritis occurred in six of Dickson's 158 cases the spine was involved in two places once, the spine and knee in two cases, the spine and both hips once, and the knee and wrist, and hip and wrist once each The tuberculous, or unusual, nature of the polyarthritis was suggested by its asymmetry and the successive, not coincident, involvement of the several joints

Rare features of tuberculous arthritis are perforation of abscesses of the hip joint, sequestration of parts of the femoral head into the bladder and lengthening of a leg due to stimulation of growth centers by increased vascularity (Henderson) Armstrong noted tuberculosis in a joint which was the site of exostoses typical of metaphysical aclasis, and the presence of extensive tuberculous synovitis in a joint without appreciable stiffness, pain or deformity and without roentgenographic bone changes or pathologic (biopsy) involvement of articular cartilage or bone

Pathology The usual synovial reaction was described (Ghormley and Deacon)

From a study of four postmortem specimens Compere and Garrison concluded that tuberculous spondylitis begins in cancellous vertebral bone and encroaches on vertebral cartilage and intervertebral disks Cartilage and *annuli fibrosi*, being resistant to tuberculous invasion, persist longer than bone As the disease progresses bone is destroyed by the extension of tuberculous tissue which may or may not contain typical tubercles The anterior common ligament is elevated from the vertebral bodies, the disease extends along the spine beneath this longitudinal ligament, involving vertebrae above and below but not the disks until late Abscesses may push back into the vertebral canal but do not tend to penetrate dura The tuberculous processes were compared to those in osteomyelitis

Vertebral osteomyelitis also seems to begin in cancellous bone via hematogenous implants, as Compere and Garrison noted, it could hardly begin in disks since they

contain no blood or lymph vessels. In contrast to their fate in tuberculous spondylitis, disks in osteomyelitis are quickly destroyed and formation of new bone and vertebral fusion may occur. When tuberculous spondylitis is complicated by pyogenic infection the pathologic reaction is mixed, new bone formation from the pyogenic infection is associated with tuberculous bone destruction.

A case of extensive tuberculous spondylitis which healed under conservative treatment supplied Finder with interesting pathologic material when the patient finally died. The destructive bone changes and osteoporosis, so common in the active stages of tuberculosis, were absent. Bone lesions had healed and osteosclerosis had developed, complete union by bony fusion had occurred between two vertebrae. Finder concluded that healing may occur spontaneously, and vertebral bone sclerosis, as seen in roentgenograms, may indicate an old healed tuberculous lesion, not necessarily osteomyelitis.

Roentgenographic Features They have been presented in previous reviews. They are often only suggestive, not pathognomonic, of tuberculosis. In the early stage none may be present. Later one or more of the following features will be found (Dickson, Henderson): uniform thinning of bone cortex, destruction or thinning of articular cartilages, decalcification of bone ends, lack of new bone formation, presence of foci of bone destruction usually in epiphyses, failure of the process to extend along the shaft but a tendency to involve the neighboring joint. Bone abscesses are indicated by rarefied portions, it is not uncommon to see little notched rarefied areas on tibial or femoral margins at synovial insertions. In a knee the intercondylar notch is often enlarged. In an elbow the olecranon process may be wedged deeply between humeral condyles. In advanced stages the picture is one of destructive arthritis, which is usually more extensive than roentgenograms suggest. The incidence of the various roentgenographic features in 32 cases was noted by Taylor, Ferguson, Kasabach and Dawson. Roentgenograms in tuberculous and gonorrheal arthritis possess several features in common but the length of time required to produce changes in tuberculous arthritis is likely to be ten to twenty times as long as that required to produce corresponding changes in gonococcal arthritis.

Differential Diagnosis Early differential diagnosis is very important since only then, if ever, is cure with function possible. Diagnosis may be difficult because tuberculous arthritis may be multi-articular and atrophic arthritis occasionally may long be monoarticular. Collins and Cameron noted a case illustrating the diagnostic difficulty arising because of the following circumstances: (1) The insidious monoarticular onset of some cases of multiple, nonspecific arthritis, (2) the coexistence in the patient of some visceral tuberculous lesion which may or may not influence the course of nontuberculous polyarthritis, (3) the possible occurrence of a single tuberculous joint superimposed on nontuberculous multiple arthritis, (4) the occasional incidence of true tuberculous arthritis in two or more joints, (5) the comparative infrequency of nonspecific arthritis of a hip in patients of less than

middle age and the tendency to suppose such a condition to be tuberculous, (6) modification of the course of nonspecific arthritis due to early immobilization, (7) the possibility that there exists an atypical tuberculous form of polyarthritis—tuberculous rheumatism

Consideration of the following factors was currently stressed (Henderson, Dickson, Ghormley and Deacon) as useful in differentiation Age Tuberculous arthritis generally occurs before the age of 14 years However Dickson and Henderson not infrequently noted its appearance in patients 50 to 65 years old Family history Familial tuberculosis was present in only 8 per cent of Henderson's cases Coincident pathology Tuberculosis occurred in sites other than joints in 44 per cent of Henderson's cases, most often in lungs Precipitating factors Recent trauma, 6 to 12 weeks before onset of symptoms, followed by a prodromal quiescent period, was not uncommonly noted About 50 per cent of patients with tuberculous arthritis think they traumatized the affected joint before onset of symptoms but Henderson believes that trauma really acts as a precipitating factor in only 13 per cent of cases Appearance of joint The presence of a chronic or subacute monoarthritis should make one suspect tuberculosis The characteristic appearance is that of a boggy joint without evidence of acute inflammation, a doughy enlargement due to swollen synovia, not to hydrops Generally little or no fluid can be felt or aspirated from a tuberculous joint in contrast to the hydrops common in nonspecific arthritis Much fluid is evidence against, rather than for, tuberculosis Muscle atrophy is present, often early and extreme—out of proportion to the duration of illness Symptoms The rather late appearance of articular pain and tenderness suggests tuberculosis, in other arthritides pain is usually early and notable Course A feature of tuberculous arthritis is its indolent chronicity with periods of remission and exacerbation, the general trend is one of progression and persistence of symptoms, a residuum of symptoms remaining even in the so-called remissions

Biopsy and Guinea-Pig Tests The diagnosis of tuberculous arthritis is not easy Biopsy is sometimes necessary Pathologists are usually able to make a definite diagnosis but in doubtful cases guinea-pig tests are necessary Studying 175 cases of suspected tuberculous arthritis, W E Swift noted the relative accuracy of diagnosis made on the following clinical data, roentgenograms, frozen-sections of tissue, paraffin-sections of tissue, inoculation of guinea pigs Each method was subject to some error

Tuberculin Reaction A positive tuberculin reaction affords only presumptive evidence of tuberculous joint disease unless all other possible active tuberculous foci can be excluded A negative reaction in the absence of certain modifying factors (overwhelming tuberculous infection, advanced sepsis, anemia or other grave disease) can eliminate the diagnosis of tuberculosis with some certainty Collins and Cameron recommended Parke-Davis' Tuberculin PPD (Purified Protein-Derivative) for such tests

Treatment In 50 per cent of the 400 cases in which arthrodesis was

done at The Mayo Clinic for tuberculous spondylitis there was arrest of the disease, according to Henderson. Eradication of tuberculous bone is not possible and the operation of fusion of laminae and articulating processes posteriorly, if combined with general treatment, seems merely to hasten the process of arrest of the disease. For tuberculosis of the hip arthrodesis by combined intra-articular and extra-articular fusion was favored; results were successful in 90 per cent of 46 cases. The conservative nonsurgical treatment for tuberculous knees is preferable in children but not in adults, in the latter, surgical treatment is preferable because of the economic problem. Whether arthrodesis is to be done depends on the condition of the knee and the patient's general condition, social status, temperament, and so forth. A low grade tuberculous arthritis of a knee may exist for years with little trouble to one able to govern his activities, in such cases arthrodesis should not be insisted on. Bony fusion was successful in 89 per cent of Henderson's 248 patients with tuberculous knees, the surgical mortality was zero. For the treatment of quiescent tumor albus and tuberculous pseudoarthrosis in children Delahaye developed a completely extra-articular method of arthrodesis. In a tuberculous hip the production of solid, bony ankylosis is the best result that can be obtained, even so abscesses may develop and sinuses may continue to drain indefinitely, according to Adams.

"TUBERCULOUS RHEUMATISM"

Definition, Types Poncet (1897) described two varieties of tuberculous rheumatism or polyarthritis: an acute or subacute form and a chronic form. Basis for the diagnosis included a family history of tuberculosis and the presence in the patient of true tuberculous arthritis occurring before, with, or after the onset of the "tuberculous polyarticular rheumatism." Since Poncet, others have varied the clinical picture and extended the basis of diagnosis. According to Copeman, one variety resembles acute rheumatic fever in that joints are successively affected without permanent lesion or disability but it differs from rheumatic fever in the absence of carditis and resistance to salicylates. The second variety is that of a transitory or more chronic polyarthritis eventually becoming localized in one of the joints first affected.

Clinical Features Admittedly the clinical features of the entity have never been set forth with unmistakable clarity. Kubirschky's criteria for a diagnosis of tuberculous rheumatism were repeated^{145, 247}. Reputed clinical features are as follows (Copeman, Dickson): (1) tuberculosis often in the affected person's family, (2) visceral tuberculosis often in the affected person, (3) involvement of fewer joints than in most types of polyarthritis and a predominant involvement of one joint, (4) presence of more fever than in other forms of polyarthritis, (5) a condition refractory to salicylates, (6) absence or rarity of carditis, (7) isolation of Koch's bacillus from synovial fluid in certain cases, (8) blood cultures positive for tubercle

bacilli (Reitter-Lowenstein technic, 1934), but only during certain phases of the disease

Representative Cases Copeman found 12 cases in the literature which seemed to fulfill these criteria. Most of them were reported from France, none from England or America in 22 years. Six of the 12 cases seemed to represent an intermediate type, "not so far recorded in the English literature," in which pathologic reaction in patients' joints were atypical but injections of joint fluid produced tuberculosis in guinea-pigs.

Of the 12 patients, 10 were females, two were males. Age onset of arthritis averaged 28 years (range 17 to 66 years), three gave a history of previous attacks with increased joint damage after each the joints in the intervals being quiescent, eight noted febrile onset, four of six patients were unrelieved by salicylates, three gave a family history suggestive of tuberculosis, four previously had disease suggestive of tuberculosis, two ultimately developed frank tuberculous arthritis in one of the affected joints, all of five patients tested had positive tuberculin tests, joint fluid from eight cases and blood from one case were injected into guinea-pigs, results were "positive" for tuberculosis in six, doubtful in one, negative in two, in four cases synovial tissue at biopsy revealed "chronic inflammation", in two specimens acid-fast bacilli were seen on staining, in five cases ankylosis occurred in one or more joints.

Applying these criteria and tests to 42 of his own cases of "typical rheumatoid arthritis" Copeman detected evidence of an associated tuberculous factor in 12 cases.

(Two of these cases were abstracted in the third review—Ed.)

He concluded that a proportion (possibly 30 to 40 per cent) of all patients with true rheumatoid arthritis can be shown to suffer or have suffered from a low-grade tuberculous infection, which in certain cases at least may be related to the course of the polyarthritis, and that "tuberculous rheumatism" cannot be distinguished by clinical means from rheumatoid arthritis of other causation. Features most suggestive of the condition were the increased incidence of tuberculous antecedents (present in six of his own 12 cases), subsequent development of classical tuberculous arthritis (in two of the 12 cases), the discovery, after injection of tuberculin, of silent foci of tuberculosis (in two cases), pyrexial onset of the arthritis with marked fatigue (three of 12 cases), increased sensitivity to tuberculin in all of 12 cases, a tendency for the condition to progress by recurrent attacks with intervening quiescent periods, the isolation of tubercle bacilli from the blood (sent by Copeman to Lowenstein) of 11 of the 12 cases. Specimens of blood from 30 patients with rheumatoid arthritis in whom Copeman found no evidence of associated tuberculosis were also sent to Lowenstein, in only one case was the culture "positive for Koch's bacillus," the case of a child whose father was being hospitalized for tuberculous adenitis.

Pathogenesis, Pathology Copeman's interpretation follows. Most persons have been infected with tuberculosis in early life but have overcome the infection. In certain cases focal areas may become quiescent or slightly

reactivated but "silent" Certain cases of "rheumatoid arthritis of unknown cause" are cases of tuberculous rheumatism, the infection originating in a chronic or periodic leakage of toxic material, or of actual bacilli, possibly of attenuated virulence, from such a tuberculous focus This primary focus is of such low virulence as to cause no general symptoms but it produces in "susceptible" joints an inflammation different from classical tuberculosis The histologic appearance of synovia generally reveals "non-specific inflammation" with subendothelial collections of round cells as found in rheumatoid arthritis Perhaps the latter cells represent a halfway stage, due to altered bacterial virulence, between nonspecific and true tuberculous changes Perhaps the affected joints are sensitized by tubercle bacilli, their toxins or virus, this sensitization may be nonspecific to the extent that subsequently it can be activated by streptococci or other bacteria, not necessarily tubercle bacilli, thus presenting a "symbiotic cause" of chronic polyarthritis

Conclusion The consensus of current opinion is that this entity is not established Those who refuse to accept it base their position on the failure to find characteristic histologic changes in repeated examinations of tissue from supposed cases and the negative results of guinea-pig tests It was agreed that there seems to be no good reason why tuberculosis cannot produce a polyarthritis just as streptococci or gonococci do One cannot categorically deny the possible influence of associated visceral tuberculosis on the production and course of polyarthritis However, no definite clinical syndrome of tuberculous rheumatism has been established, no consistent experimental or laboratory evidence has been produced in support of the clinical evidence offered, and in very few of the reported cases has proof of tuberculous origin been forthcoming According to Ghormley and Deacon, "To date no proof of the tuberculous etiology of chronic proliferative arthritis exists It may be proved at a later date but this seems unlikely to us"

SYPHILITIC SYNOVITIS AND ARTHRITIS CHARCOT JOINTS

Charcot Joints The incidence of Charcot's disease in neurosyphilitic patients is not great It developed in 6 per cent of 744 tabetic patients (Moore, 1933) Epstein's patients with Charcot joints rarely present themselves because of symptoms referable to their nervous system but cause of joint disease The condition was not accompanied by any marked symptoms of tabetic disease

Pathogenesis Epstein accepted the theory of Wile and Butler (1930),—the joint changes are always associated with destruction of the afferent (proprioceptive) nerves, rendering the joint tissues insensible to trauma Under these conditions each minor injury or even physiologic trauma produces further articular pathologic lesions which accumulate to form the end picture of a Charcot joint Many restrict the use of the term "Charcot

joint" to the arthropathies of neurosyphilis. But articular disintegration similar to tabetic arthropathies may occur with syringomyelia, myelitis, poliomyelitis and gunshot wounds of the cord.

Roentgenograms Except in early cases the changes are fairly typical swelling and increased density of soft tissues, excess fluid in joints and tissues, diffuse sclerosis of bone with atrophy, erosion of joint surfaces, production of new bone, pathologic fractures, loose bodies in the joint, calcification in periarticular tissues, subluxations or dislocations (Epstein)

Cytology of Synovial Fluid Collins studied the fluid from a grossly disorganized Charcot joint of a patient who had advanced tabes. The total cell count was 250 per cu mm, with 25 per cent polymorphonuclears and 43 per cent lymphocytes.

Treatment Neurologists and syphilologists have been able to do little in these cases. Orthopedic management is more important than antisyphilitic treatment, according to Epstein, who presented eight cases in which antisyphilitic treatment alone was insufficient to check the progress of arthropathy. Conservative treatment to reduce pain and swelling and to protect the joint from trauma includes much rest, avoidance of weight-bearing, immobilization in a splint or cast if necessary, local application of heat, especially diathermy, non-weight-bearing exercises, if fluid is present, repeated aspiration to prevent undue capsular and ligamentous stretching, later suitable orthopedic supports for affected joints. Operative treatment includes correction of fractures, removal of draining sinus tracts, amputation of totally disintegrated regions such as an ankle or foot that has become "a veritable bag of bones," correction of valgus or varus position of an ankle by osteotomy, and other procedures.

Fever Therapy and Chemotherapy as Prophylaxis Since the only effective treatment of Charcot's disease is prevention it is appropriate to note that electropyrexia represents a distinct advance in the treatment of early syphilis and of neurosyphilis particularly when combined with chemotherapy (Simpson, Neymann, Lawless and Osborne). "Tabes is very favorably influenced by electropyrexia." Neymann, Bennett and Simpson noted relief from intractable root pains, gastric crises, ataxia, cord bladder, head pains, and paresthesia. Fever therapy should not be expected to affect Charcot joints.

UNDULANT (MALTA) FEVER, BRUCELLOSIS, BANG'S DISEASE

Incidence A discussion of undulant fever is appropriate because the disease commonly affects muscles and joints. Further data were presented on the increasing prevalence and recognition of the disease in the United States and in the separate states (Hardy, Jordan, and Borts), in Kentucky (Beatty), in Pennsylvania (Ervin, Hunt and Niles), in Wisconsin (Sprague), in Texas (Winans), and in the Tanganyika Territory (Wilson). Reported cases in the United States numbered 1,887 in 1934, 1,897

in 1935 The highest incidence is in Iowa, Vermont, Missouri and Kansas There were 705 new cases in Iowa According to Winans, brucellosis in office practice in Texas is more common than unsuspected syphilis Among 295 office patients studied in sequence, 10 had positive agglutination tests for undulant fever, seven gave a positive Wassermann test Discarding patients with no other signs of the disease the corrected total of cases of clinical undulant fever was 1.7 per cent of the 295 patients

Economic Importance Undulant fever is the greatest medical problem in the cattle industry Apparently 20 per cent of all cows in Texas (Green), 10 per cent of all milk goats, and 13 to 16 per cent of cows in the entire country have or have had the disease (Vreeland)

Symptoms "A disease of many forms, undulant fever in the human has no parallel, it may be latent or fulminating, acute, subacute, or chronic, local or general, febrile or afebrile, inflammatory or noninflammatory" (Green) Its symptomatology is protean and widespread and may be classical to the experienced physician but vague and mixed to the unsuspecting practitioner Textbook descriptions are inadequate and ordinarily would not lead to a diagnosis Laboratory data and the incidence of various symptoms were studied in 705 cases by Hardy, Jordan and Borts, in 300 cases by Dalrymple-Champneys, in 35 cases by Beatty, in 12 cases by Ervin, Hunt and Niles Dishongh regards the disease as without cardinal symptoms, as one "which may resemble any disease known to science" Symptoms are those of septicemia Commonest were weakness, fatigue, malaise, fever, drenching sweats, headache, "rheumatic pains" in various muscles and joints, in back, neck, chest or extremities, anorexia, constipation, chilliness or chills, epigastric, abdominal or pelvic pain, palpitation, depression, weight loss There were a host of less common symptoms Occasional complications were sinusitis, pyelitis, pleurisy, mucous colitis, seborrheic dermatitis, leg ulcers^{31, 127}

The fever is usually intermittent, remittent or undulating, but this type is not always present (Gottlieb) Secondary anemia and leukopenia with relative lymphocytosis are usually present but leukocytosis occasionally occurs²⁰⁹

Five clinical types were spoken of 1 The intermittent type, which is the commonest, is of subacute onset and there is an intermittent afternoon fever, the average duration is 1 to 4 months 2 The ambulatory type comprises 25 per cent of cases in the United States, the illness is short and mild and is featured by weakness and fever which may be high but which is quite or almost unrecognized by the patient, who may continue at work 3 The undulant type (15 per cent incidence) is marked by successive relapses, decreasing in intensity and duration 4 The malignant type (2 per cent of cases) is of sudden onset, it is an overwhelming disease of rapid, fatal termination 5 The subclinical type is unrecognized by the patient, it is asymptomatic, affects exposed persons and is discovered by the presence of agglutinins The disease presents two phases 1 The acute phase may have

an insidious or sudden onset. Prodromes are malaise and general aches, later symptoms are chill, fever, headache, backache, neckache, sweating, weight loss, acute arthralgia, abdominal pain, nausea, vomiting. 2 The chronic phase may follow the acute, or may appear independently, and is characterized by malaise, low grade fever, growing weakness, weight loss, general aches and pains. The disease is most commonly misdiagnosed as typhoid fever, influenza, paratyphoid fever.

Duration of the disease is very variable according to Beatty, who studied chronic cases, it may last four weeks to 17 years (av 37 months), according to Carpenter and Boak it generally lasts ten days to six months, occasionally six years (av three months). To determine the natural course of the disease without "specific treatment" Carpenter and Boak treated 26 patients symptomatically only, the duration was two to 72 (av 12.5) weeks.

Symptoms referable to muscles and joints. In different reports the incidence of articular symptoms was variable but generally notable. arthropathies were present in 31 per cent of Simpson's 175 cases (1930), in 32 per cent of Hardy's 375 cases which also included one case of hydrarthrosis and one of osteomyelitis. Undulant fever in Iowa has been characterized by arthritis, acute or chronic, septic or nonseptic, by spondylitis simulating Pott's disease, and by osteomyelitis (Hardy, Jordan, Borts). Wilson regarded as "very characteristic" burning pains in certain joints, especially wrists, ankles, elbows. Dalrymple-Champneys noted "arthritis and arthralgia" (no further description) in 20 of 300 cases. Four of the eight patients noted by Neumann had "rheumatic pains", one other patient had arthritis of a hip joint. Other cases of undulant fever with arthritis were noted ^{79, 147, 511, 555}. Two of Vreeland's patients had four joints severely affected, one patient, six joints. A patient of Winans had fever, pain, swelling and stiffness in ankles, wrist and spine, a negative agglutination test and blood culture but a strongly positive skin test and rapid response to appropriate treatment. Cases with arthralgia and myalgia were noted by many ^{168, 555}. Among Beatty's 28 patients, 24 had backache, 23 had neckache. According to Sprague "rheumatic manifestations," pain and swelling in joints, have been reported in about 50 per cent of cases, Vreeland often noted swollen, tender but not red joints, especially shoulders, ankles, knees, hips and sacro-iliacs.

Kulowski noted five cases of undulant fever affecting the osseous system: two cases of spondylitis, one of acute arthritis of a wrist, two of osteomyelitis (of the humerus in one instance, of skull and ribs in the other).

Case 1 Brucellosis osteomyelitis of left humerus. The patient noted insidious onset of pain and stiffness of the left arm and shoulder, which continued for four years without constitutional reactions. An abscess finally formed and was drained. Pain recurred and a deltoid sinus was incised. Brucella organisms were recovered, agglutination test was strongly positive.

Case 2 Brucellosis spondylitis. A month after "the end" of a 6½ months'

undulant fever, low back pain developed without constitutional reaction. The condition became acute and febrile. Agglutinins for *Brucella* were present—1:640 and 1:160. Spinal fusion was done.

Case 3 Brucellosis spondylitis. Low backache developed, remained insidious for seven months, then became acute. Roentgenograms showed destruction of lower lumbar interarticular facets with abscess formation. A huge prevertebral abscess was drained, *Brucella* was recovered.

Case 4 Brucellosis of wrist joint. Undulant fever developed, agglutination, 1:640. Three months later acute painful swelling affected a wrist from which pus was recovered.

Case 5 Brucellosis osteomyelitis of skull and ribs. Undulant fever developed in May. An abscess appeared over the ribs anteriorly in June, another abscess over a hip in September, other rib abscesses in October 1930. In September 1933, a skull lesion was drained, pus was sterile.

Intermittent hydrarthrosis associated with undulant fever was noted once each by Baker (1928, 1929), by Weil (1930), by Hardy and associates (1931) and by Simmons (1935). Sharpe has reported another such case.

A young man, in 1929, had painful swellings of knees, right ankle and right wrist. These persisted for 6 weeks, recurred at irregular intervals in the knees for a year. Fever was not noted. The knee swellings returned in 1933, were definitely intermittent, sufficiently painful to require repeated aspirations, and were associated with afternoon fever to 102° F. Anorexia and loss of 20 pounds had occurred. The swellings occurred in 7 to 10 day cycles, between times they disappeared completely from the left knee, incompletely from the right and were painful only at their highest level. The patient had lived on a farm, adjacent to those affected with contagious abortion, and had drunk cow's raw milk. Roentgenograms indicated "rheumatoid arthritis." Agglutination tests with *Brucella* were 1:400. Cultures of blood, urine and synovial fluid for *Brucella* were repeatedly negative. Fever and articular swellings were unrelieved by a course of Lederle's undulant fever vaccine, only partially and temporarily relieved by artificial fever therapy. Fever, hydrops and strong agglutination reactions have persisted.

(Was this really a case of undulant fever?—Ed.)

With Scott, O'Donoghue, who recently noted a septic hip due to *Brucella* (1933), reported a case of degenerative myositis from *B. melitensis*.

The patient had fever, agglutination 1:320, a positive skin reaction and was treated by goat serum and brucellin. During treatment shoulders and deltoids became painful. Within a month atrophy of supraspinatus and infraspinatus muscles and of the deltoids occurred but disappeared 10 months later. Biopsy disclosed degenerative myositis, interstitial round-cell infiltration, sterile cultures.

Diagnostic Criteria Laboratory Data A diagnosis of undulant fever depends on the presence of a characteristic or a suggestive history supported by some of the following:

1 Agglutination Tests The agglutination test is the most valuable diagnostic test after the first two weeks of the disease (Ervin, Hunt and Niles), it is most dependable in the active stage of the disease or when patients have recovered recently (Keller, Pharris and Gaub). Agglutinins against *Brucella* organisms are generally significantly present after 5 to 14

days of illness (Dalrymple-Champneys, Sprague) but it may take several weeks for tests to be definitely or strongly positive (Gottlieb) The agglutinin content of blood may change rapidly, repeated tests are often necessary before a positive test is obtained (Beatty, Dalrymple-Champneys) Titers are generally present in dilutions 1:80 or higher (Gottlieb, Sprague) but even in definite cases of brucellosis, titers may be low 1:50, 1:10, or even negative (Beatty, Sprague) Five per cent of patients never develop agglutinins (Beatty) Of 100 cases seen by Huddleson, Johnson and Bates, agglutinin titers were negative or less than 1:50 in 33 per cent Among Dalrymple-Champney's 255 cases, the average titer was 1:1500, it rose as high as 1:2500 and in only one case was it less than 1:100 Among Beatty's 35 cases the titer was 1:100 or over in 26, 1:50 in six, 1:25 in one and negative (but with positive skin tests) in two cases A negative agglutination test means either that brucellosis is absent, or that the disease is present but there is no immune response (Kemp) Agglutinins may be present for months or years after clinical recovery and titers were frequently as high as 1:640 after 4½ years (Dalrymple-Champneys) (Meanwhile an unrelated atrophic arthritis could develop Therefore every polyarthritis with positive agglutinins for *Brucella* must not be attributed to brucellosis—Ed) After clinical recovery titers usually fall rapidly, a continued high titer suggests latent activity Donham and Fitch developed a modified technic to discover agglutination earlier

2 *Precipitin Tests* Sera from patients with positive agglutination reactions also gave positive precipitin reactions with one or more polysaccharides but Higginbotham and Heathman consider the precipitin tests less practical than agglutination tests

3 *Complement-Fixation Tests* Although Thomsen (1931) found these positive oftener than agglutination tests, others^{200, 262} found them more difficult and not as reliable as agglutination or precipitin tests

4 *Intradermal Test* The technic and interpretation of this test were again described^{81, 127, 298, 581} *Brucella abortus* antigen is used Tests become positive after 7 to 11 days of disease (Sprague) A positive test is especially helpful for diagnosis in active cases when agglutination tests are negative (Ervin, Hunt and Niles) A diagnosis should not be made only on the basis of a positive skin test 20 per cent of residents in certain communities give positive tests (Carpenter and Boak) Tests were positive in 5 per cent of one group of 576 persons, living or working under conditions favorable to *Brucella* infection (Keller, Pharris, and Gaub) Kemp considered them more reliable than tuberculin tests in tuberculosis, a positive test may be incidental to a given diagnostic problem as it indicates previous as well as active infection (Gottlieb)

(The antigen is irritating Controls should always be tested simultaneously with suspects—Ed)

When it is desired to study both agglutination and intradermal tests,

agglutination tests should be done first because injections of the amount of material used for skin tests will of themselves promote agglutination reactions in titers of 1 50 to 1 200, thereby providing a source of error (Winans)

5 *Cultures* The organism may be isolated by special technic^{127, 579} from blood, urine, feces and other sources. Cultures of blood are more successful than those from other material, even so they are often negative, difficult to make, and less often used for diagnosis than other tests^{208, 511}. However, much can be learned therefrom regarding types of strains and they should be made oftener²³⁶. They usually become positive 3 to 15 days after the patient's inoculation⁵⁵⁵. They were positive in 16 of 85 cases (Huddleson and associates). Poston and Smith recovered *Brucella* from spinal fluid by a new technic whereby the germs can be grown after being precipitated by specific agglutinating serum.

6 *Guinea-Pig Inoculations* These are unsatisfactory as the test requires 4 to 6 weeks' observation and lesions resemble tuberculosis (Kemp).

7 *Opsonophagocytic Activity of Blood* This test was originated by Huddleson, Johnson and Hamann (1933), its value in determining a patient's immunity was confirmed by Keller and associates, who discussed technic and interpretation. With it, in conjunction with the skin test, one can determine which patients are susceptible, infected, or immune to undulant fever.

A low phagocytic activity and a negative skin test indicate susceptibility to brucellosis. A low or negative phagocytic activity with a positive skin test indicate infection without immunity. Marked phagocytic activity indicates developing or established immunity. Marked phagocytic activity and a positive skin test indicate that fever in a given case is due to some disease other than undulant fever.

8 "*Therapeutic Test*" Most of Beatty's patients with undoubted brucellosis noted accentuation of symptoms, malaise, general aching, as a reaction to intramuscular injections of undulant fever vaccine. Beatty considered this reaction of diagnostic significance.

TREATMENT OF UNDULANT FEVER

After reviewing 67 reports Carpenter and Boak regarded the efficacy of specific therapy unproved. The disease is self-limiting, subject to spontaneous remission or cure. They found no definite evidence that "specific therapy" shortened the disease, symptoms lasted an average of 12.5 weeks in those treated "specifically," 11.3 weeks in those treated symptomatically. General measures for the disease were again stated^{127, 581}.

Chemotherapy, Intravenous Antiseptics Various chemicals, arsenicals, dyes, acriflavine, and so forth, produced no beneficial effect unless a febrile reaction was induced^{31, 79, 299}.

Specific Vaccine Twenty-seven reports noted results in 350 patients treated with stock or autogenous vaccines. Results obtained had little to do

with the type of vaccine used but depended on the production of systemic reactions⁷⁹ Among 21 other patients only four were benefited by stock vaccine, only one of six benefited by autogenous vaccine (Dalrymple-Champneys) It was considered "beneficial" by Dishongh, "helpful but not curative" by Winans, "fairly satisfactory" by Beatty all of whose 23 patients were improved, some markedly, others slightly

Toxic Filtrates These produced no effect unless "shock" was induced (Carpenter and Boak)

Brucellin This seemed useful to some²⁷⁵, in 100 cases the average illness before treatment was 159 days, after treatment, 18 days

Antiserum Results with convalescent and animal sera noted in 13 reports were generally favorable, not spectacular (Carpenter and Boak) Superior to his older serum is Foshay's new antibrucellosis (horse) serum which is definitely antitoxic according to Bannick and Magath Poston and Smith treated two patients successfully with intrathecal injections of human immune serum Two patients were successfully treated with immunotransfusions by Creswell and Wallace who used the opsonophagocytic index in selecting donors

Foreign Protein Therapy Wilson, and Carpenter and Boak occasionally noted rapid recovery and excellent results from the shock and fever reactions of T A B (triple typhoid) vaccine Results in 12 cases of Ervin, Hunt and Niles were "uniformly successful" because of febrile reactions which presumably stimulated specific or nonspecific immunity After three to six doses of the vaccine, symptoms cleared and agglutination tests became negative Nine of the 13 other patients were also definitely helped thereby (Dalrymple-Champneys)

Fever Therapy Carpenter and Boak treated three patients with artificial fever two were promptly cured, one patient's symptoms, including arthritis, were stopped but a year later "the specific arthritis" returned Recalling the good result noted by Simmons (1935) who treated by means of artificial fever a case in which the disease was associated with severe hydrarthrosis, Prickman and Popp treated four patients without arthritis Prompt results were obtained with three fever sessions, each for five hours at 105 to 107° F Curiously the natural fever continued until the last fever session, then stopped rather abruptly, not before *Brucella abortus* in vitro can survive 24 hours at 107° F⁵⁴⁵ Therefore fever therapy alone probably does not kill the bacteria in vivo, corollary cytologic and immunologic reactions are stimulated

Fouadin (Antimony Bis-Pyrocatechin Disodium Sulphonate) This substance injected intragluteally benefited eight of Neumann's patients

Criteria of Cure, Mortality Angle's (1935) criteria of cure were (1) disappearance of subjective symptoms, (2) increasing weight, (3) gradual disappearance of fever, (4) lowering of agglutinin titer, (5) return of normal blood picture, (6) subsidence of neurologic symptoms The reported mortality is 1 to 4 per cent, in severe outbreaks, however, it may be as high as

13 per cent^{511, 555} Death in one series resulted in two of 100 cases²⁷⁵, in nine of 290 other cases,¹²⁷ in one of 26 patients,⁷⁹ and one of 35 cases³¹ Gottlieb's patient at death exhibited usual features, splenitis, lymphadenitis also, rare features subdiaphragmatic and hepatic abscesses

Prophylaxis This can be accomplished by using only boiled or pasteurized milk, and by inspection of herds—the use of blood tests for all cows and goats and the segregation, or preferably destruction, of affected animals^{31, 211}

TYPHOIDAL SPONDYLITIS “TYPHOID SPINE”

Cases of typhoid fever, especially “typhoid spine,” are now rare in the United States A few members of the Civilian Conservation Corps recently developed typhoid fever in Texas, one developed “typhoid spine” (Bowen and McGehee)

Positive blood cultures proved the diagnosis of typhoid fever in a boy, aged 15 years After desperate illness for two months he convalesced one month, then developed dorsal scoliosis, lumbar pain and rigidity Roentgenograms showed typhoid spondylitis in various stages Treatment included immobilization of the spine on a Bradford frame, later a brace was worn for six months

Typhoid spondylitis may occur during the fever or during convalescence It produces paroxysmal attacks of intense pain, tenderness, and muscle spasm, generally lumbar Roentgenograms show localized areas of rarefaction near corners of vertebral bodies, thinning of disks, subsequently the development of a heavy bony bridge about the focus and disk Suppuration has not been noted

Campbell and Greenfield found post-typhoid suppurative osteitis in a case previously called “rheumatism”

In 1922 the patient, a young man, had typhoid fever Long afterward he was still a typhoid carrier Ten years later, without intervening illness, he developed a painful left arm, diagnosed “rheumatism” Pain recurred the next year without fever, rose spots, splenomegaly or other features of typhoid fever A bone abscess in a humerus was drained, a pure culture of *Bacillus typhosus* was obtained therefrom The agglutinin titer was 1:250

MENINGOCOCCIC ARTHRITIS

Joints are involved in 4 to 7 per cent of cases of meningococcic meningitis²⁴⁶ A case of meningococcal suppurative arthritis of cryptogenic origin was reported by Campbell and Greenfield

A colored infant, aged 15 months, developed an inflamed knee joint with fever of 103° F Pus was removed therefrom, the child improved immediately Cultures of pus revealed *Neisseria intracellularis* which agglutinated with polyvalent meningococcus agglutinating serum up to a titer of 1:100 of the serum The patient did not have meningitis

Fever Therapy for Meningococcic Infections Sustained artificial fever at 107° F is effective against certain strains of meningococci Thermal deathtime studies by Bennett, Person and Simmons showed that most strains died out on a water bath at 106.8° F, within eight hours Two cases of proved chronic meningococcic infections (neither with arthritis), were cured by artificial fever Artificial fever therapy will probably not replace serum therapy, because of the danger of severe cerebral edema and medullary failure fever therapy is probably contraindicated in acute meningitis It may have a place as adjuvant therapy in subacute or chronic meningococcic infections unrelieved by serum or in meningococcemia

PYO-ARTHRITIS PURULENT (SEPTIC) ARTHRITIS

Acute septic arthritis arises in three ways Bacteria reach the joint (1) By direct introduction into joints from penetrating wounds, knees are thus affected most often but this is the least common type of septic arthritis in civil life, (2) by direct extension of para-articular infection, most commonly osteomyelitis, into a joint, (3) by the blood stream from distant foci of infection This type, "metastatic arthritis," is the most frequent and may follow measles, scarlet fever, gonorrhea, pneumonia, meningitis, subacute bacterial endocarditis, in association with any septicemia, for example, from abscesses in tonsils, teeth, or prostate, from boils or infected skin, from scratches or wounds Of seven cases of septic arthritis of hips in children seen by Freiberg and Perlman, six originated from otitis media or mastoiditis, one from trauma, one from unknown source Of 16 cases affecting knees seen by Eggers, seven originated from puncture wounds or other trauma, one from pharyngitis, three from pneumonia, one from osteomyelitis, four from other causes Regan's four cases in hips arose from cystitis, sinusitis, oral infection, tonsillitis

Invading bacteria are generally *Staphylococcus aureus* or hemolytic streptococci, less commonly other streptococci, gonococci, pneumococci, meningococci, typhoid bacilli, influenza bacilli (Harris) In current series organisms recovered were staphylococci, hemolytic and nonhemolytic streptococci and pneumococci (Eggers, Freiberg and Perlman, Regan)

Clinical findings as currently reviewed are usually definite abrupt onset of pain, redness and swelling of a joint, often after trauma, capsular distention, muscle spasm in flexed position, marked constitutional reactions, fever, leukocytosis, sometimes positive blood cultures Aspiration of the joint reveals pus and confirms the diagnosis Badgley and his colleagues reported 113 cases of septic hips

Pathology Depending on the severity of infection, pathologic reactions vary from mild synovitis to a devastating articular infection that may end in death They were briefly summarized in recent articles^{9, 194, 195, 238} Most important are changes in cartilage which, once destroyed, is not replaced Variable degrees of destruction occur, not by the direct action of bacteria

but by the action of proteolytic enzymes in the leukocytes of pus, to a lesser extent by pressure and by synovial pannus. The microscopic appearance is the same in various pyo-arthroses irrespective of the invading bacteria.

Roentgenograms In the early stage roentgenograms show little or nothing in the hematogenous type of septic joints. In other types they may reveal penetrating wounds or osteomyelitic foci^{9, 238}. Later, variable degrees of destructive arthritis are seen but then roentgenograms are of no diagnostic, only of prognostic, help.

Differential Diagnosis Differentiation must be made from rheumatic fever, gonorrheal arthritis (which may also produce septic joints), juxta-articular osteomyelitis without secondary arthritis, less often hemophilic arthritis^{9, 238}. In osteomyelitis of juxta-articular bone, maximal tenderness, swelling and pain are over the epiphyseal line rather than the joint. If the joint is still not secondarily affected it moves without pain through a partial range of movement. The most valuable clinical symptom in differentiating acute septic arthritis from periarticular lesions is that the patients with septic arthritis often have severe pain on the slightest degree of passive motion, induced even when adjacent muscles are completely relaxed (Armstrong).

Diagnosis is easy when classical symptoms are present: initiating trauma or infection, fever, leukocytosis, one swollen painful joint, generally in a child. All writers emphatically urged that in case of doubt diagnostic aspirations, repeated if necessary, are urgently indicated. "Their value cannot be overemphasized." By aiding early diagnosis they provide the only sure means of protecting the joint, which will be seriously damaged or perhaps completely destroyed if diagnosis is delayed^{9, 160, 238}. According to Armstrong, "monarticular lesions should always be considered septic until proved otherwise."

(We agree that *acute* monarthritis with marked *constitutional reactions* should always be regarded as septic arthritis until proved otherwise. Commonest forms of acute monarthritis (much commoner than septic arthritis) are traumatic arthritis, nonseptic gonorrheal arthritis or gouty arthritis. In acute gouty arthritis the local pain and inflammation may be intense but constitutional reaction is usually mild.—Ed.)

When a wound occurs in the vicinity of a joint it is sometimes difficult to determine whether or not it has entered the joint. Harris' procedure is to insert a needle into the joint distant from the wound and inject a small amount of ether, if the wound penetrated the joint ether will boil out of the wound.

Complications of Septic Arthritis The following complications were noted by Badgley and his colleagues among 113 cases of septic hips: disappearance of the femoral head in 43 cases, sequestration of femoral head in 21 cases, epiphysiolysis in nine cases, dislocation of the femoral head in 34 cases, nearthrosis at the epiphyseal line with fusion of head to acetabulum or ilium in eight cases, coxa magnum in 5 cases. Freiberg and Perlman observed seven cases in which inguinal lymphadenitis and iliac abscesses

were secondary to septic hips "No similar cases have been reported previously" The question was raised Are secondary iliac abscesses unrecognized but common complications of septic hips? Hepler noted five cases of septic hips from pelvic osteomyelitis in which the bladder became markedly displaced by intrusion into the pelvis of an enormous involucre to which the bladder became attached and was displaced laterally In such cases perforation of the bladder by sequestra and production of osteovesical fistulas threaten or impend When perforation occurs, as it did in two cases, it is chronic or subacute, with the entire side of the bladder firmly adherent to the involucre so that there is no urinary extravasation or leakage, and no signs or symptoms referable to the urinary tract Therefore cystograms should be made routinely, as the condition occurred in every child with chronic suppurative arthritis of the hip and pelvic osteomyelitis which Hepler saw in the last six years

(One of us, J A K, believes these cases are very unusual and that such routine cystograms are not advisable—Ed)

Treatment Regan gave a brief historical résumé of treatment from the alpha of amputation to the omega of ankylosis Of supreme importance are early diagnosis and early *adequate* drainage Repeated aspirations, drainage through small incisions, or aspiration with injection of antiseptics are usually inadequate in severe cases Cases "cured" thereby are probably mild ones which would have recovered without surgical interference^{160, 238} Favorite methods of surgical drainage were described^{9, 15, 100, 194, 238, 449}

Patients are extremely toxic, transfusions, dietary care, relief from severe pain by narcotics are necessary¹⁶⁰

Prognosis, Results of Treatment Prognosis is generally grave Several factors determine the end result, results are better in the young than in those with joints traumatized by wear and age Results are less satisfactory in hips (Regan) than in certain other joints Some⁴⁴⁹ say that results depend to a marked extent on the type of infection, that staphylococci produce ankyloses earlier and oftener than streptococci, others say just the opposite The primary site of infection, not the germ, is the chief determining factor The presence or absence of primary juxta-articular bone disease is the important factor in persistency of trouble^{15, 160}

Of equal or greater importance is the promptness with which the diagnosis is made and drainage instituted, for this determines the degree of damage to cartilage from proteolytic enzymes in pus^{9, 238} The only good results obtained by Regan occurred when treatment was instituted within the first six days of disease Of Egger's patients, seven recovered some function, six developed ankylosis, two had amputations, one died of empyema Of patients of Freiberg and Perlman, one retained good hip motion, three developed marked limitation, three ankylosis Of the 113 patients of Badgley and associates seven retained normal function, 23 regained 50 per cent normal function, 83 developed irreparable articular damage with

numerous complications, of the latter 12 died of septicemia, two of post-operative complications

Experimental Embolic Staphylococcus Arthritis Kistler gave rabbits intravenous injections of (1) fully virulent, (2) partially sterilized, and (3) killed agglutinated and nonagglutinated saline suspensions of *Staphylococcus aureus*. Of the surviving animals that received living organisms, 100 per cent developed marked exudative arthritis with cartilaginous and osseous destruction, 53 per cent, endocarditis and suppurative pericarditis. Agglutinated and partly or almost completely sterile organisms produced even more marked and more chronic suppurative articular and subchondral lesions. Suspensions of completely sterile bacteria, whether agglutinated or not, produced no significant lesions.

RHEUMATIC FEVER

Incidence Factors which govern the incidence of this disease pertain to geography and climate, season, economic factors, age and sex.

Factor of Geography and Climate Nichol again summarized available data on the hospital incidence of rheumatic fever and of rheumatic carditis in various parts of the United States, from latitude 47° N (Spokane) to latitude 25° N (Miami). The data revealed a definite inequality in the distribution of the disease, the incidence being much less in the southern states. In West Virginia the acute stages of the disease are likely to be mild or absent but subsequent rheumatic carditis is common.⁵¹⁹

In Nebraska the disease is common.⁵⁴⁴ Christie noted that although the general incidence of rheumatic carditis was low, the hospital incidence among children in the San Francisco and University of California Hospitals was double or triple that of similar hospitals elsewhere in the country. This incidence cannot be blamed on the numerous health-immigrants to California since the incidence of rheumatic carditis is low in Los Angeles. Perhaps in northern California after an apparently typical onset and course the disease becomes "benign" and is not recognized in school examinations. In Wichita Falls, northern Texas, Whiting found the incidence of rheumatic fever and chorea to be $\frac{1}{8}$ that of Virginia, $\frac{1}{14}$ that of Boston.

(Since rheumatic carditis is more prevalent among those of lower economic strata may not his failure to include negroes have resulted in an artificially low incidence? —Ed.)

Physicians in the Mississippi Valley see about $\frac{1}{6}$ as much rheumatic fever as those in New York, according to Kinsella.

Each year from 15,000 to 30,000 deaths from rheumatic carditis occur in England and Wales, 1500 in Ireland.^{371, 393} In England and Wales 1 per cent of students entering, and 2.5 to 3 per cent of those leaving, urban elementary schools have rheumatic carditis and 1500 children under the age of 15 die therefrom each year.³⁷¹ In Ireland the incidence of rheumatic

fever varies from 1.03 per 1000 rural school population to 7.72 per 1000 urban school population. Statistics were presented on the incidence of juvenile rheumatic carditis in various cities of the British Isles^{393, 455}. Carditis was five times as prevalent as tuberculosis in Glasgow and Edinburgh schools. One-third of all London children who were chronic invalids were crippled by rheumatism in some form.

Rheumatic carditis can no longer be considered a rare disease in India. According to Banerjea's statistics rheumatic fever is almost as common in South India and Bengal as in England and the United States. It is common also in the Bombay Deccan although not as prevalent as in other countries, of 100 cardiac cases in Miraj, 47 were rheumatic (Carruthers). Thus the percentage of heart disease of rheumatic origin was actually greater than elsewhere but the carditis tended to be less severe. Kar also noted the disease in India.

Seasonal Incidence The disease was most prevalent in San Francisco in the first four months of the year⁸⁵, in Minneapolis, in early spring and late fall⁴⁸².

Social and Hygienic Factors Most of the rheumatic children seen by Ash came from poor families. Eighty-three per cent were white, 17 per cent were negroes. The relative insusceptibility of negro children suggested that malnutrition and poverty are not sole contributing factors.

Hereditary and Familial Factor Among 370 children studied by Shapiro were 201 with rheumatic carditis, 169 with nonrheumatic cardiac disorders. The incidence of rheumatic fever was three times as great in the families of the rheumatic group as in those of the nonrheumatic group.

Others noted a familial incidence of 32 per cent,⁸⁵ 24 per cent²² and 18 per cent¹⁹⁷.

Factor of Age The disease may begin at any age but further statistics again indicated that it generally begins in persons before the age of 10, especially between five and seven years^{11, 22, 80, 85, 197, 307, 455, 482, 568b}.

Factor of Sex In the new American series the sex incidence as usual was slightly greater among females, the incidence in females being from 52 to 59 per cent^{11, 85, 197}. Rheumatic chorea was much more common in females, Ash's ratio being 1 choreic boy : 2.5 girls.

The sex incidence was strongly reversed in the two series of cases from India. Seventy-seven per cent of Carruther's cases and 88 per cent of Banerjea's cases were in males. This may be due to the fact that especially in India women are more apt to be treated at home. Banerjea could not accept this idea because the relative preponderance of the disease in males prevailed in his private practice also.

GENERAL SYMPTOMATOLOGY AND PATHOLOGY OF RHEUMATIC FEVER

Swift's definition of rheumatic fever¹³⁸ affords a basis of understanding of its protean symptomatology. "Rheumatic fever is a disease of undeter-

mined etiology characterized by fever and a toxic state, and by the presence in certain organs of the body of small, disseminated focal lesions of a proliferative type. In acute stages there is also an exudation in and about the joints and sometimes in the pleura and pericardium. The term "acute rheumatic fever" has been widely objected to, in 1928 the American Heart Association dropped the use of the adjective "acute."

Clinical Phases and Types According to Coburn and others there are three clinical phases in the development of an attack: (1) an acute upper respiratory infection lasting a few days, (2) the "silent phase" immediately thereafter with no clinical symptoms and signs—it lasts for a few days to six weeks, generally one or two weeks, (3) the attack phase—the period of rheumatic manifestations varying widely in intensity and duration. Subsequently the disease runs any one of three courses: monocyclic, polycyclic or continuous.¹³⁸

Histopathologic Reaction Underlying Symptoms Swift and Derick again described the two basic inflammatory reactions, knowledge of which is so helpful in understanding the symptoms and pathology of the disease.

Two different pathologic reactions occur, exudation and proliferation, both are tissue responses to injury. An exudative reaction provides, for example, the acutely swollen joint, the proliferative reaction produces subcutaneous nodules and the myocardial Aschoff body. The two reactions are not mutually exclusive, often they coexist. The exudate consists of plasma or of synovial fluid and wandering cells, this reaction is earlier and more evanescent than the proliferative reaction. The latter appears later and is more lasting. Cells comprising the proliferative reaction are apparently not phagocytes, nor are they the epithelioid cells seen in tuberculosis or syphilis. Primitive cells, they arise from resting mesenchymal cells or from endothelial elements. Their peculiar arrangement as submiliary nodules is specific for the disease, according to some, nonspecific according to others.⁵³²

Klinge (1933) recently emphasized another feature which he believes precedes and is responsible for the proliferative tissue reaction, namely, an alteration in the intercellular mesenchymal substance demonstrated by evidences of injury to collagen fibers varying from simple focal edema to fibrinoid swelling and focal necrosis. The cause of the fibrinoid swelling is unknown. Such changes can be induced by bacteria or bacterial toxins but not by viruses. Fibrinoid swelling is also present in experimental scurvy. Thus, it is not a specific reaction. It may be a manifestation of tissue hyperergy, Klinge noted it in tissues of rabbits repeatedly injected with foreign protein.

SPECIAL CLINICO-PATHOLOGIC DATA CONCERNING RHEUMATIC FEVER

Incidence of Various Symptoms In Ash's 416 cases the initial symptom was febrile polyarthritis in 58 per cent, chorea in 21 per cent, carditis in 17 per cent. In Christie's 116 cases the initial symptom was arthritis in 68 per cent, chorea in 28 per cent, carditis in 21 per cent, tonsillitis in 19 per cent, nodules in 10 per cent, other symptoms less frequently. Among the 73

cases of Gibson and Denenholz the initial symptom was arthritis in 57 per cent, carditis in 35 per cent, chorea in 8 per cent. In adults, polyarthritis is a more common feature than carditis but in children the reverse is true a child may have only one or no joints affected (Derick)

Joints Articular symptoms were present some time during the disease in from 58 to 76 per cent of new cases reported^{11, 85, 197} including those from India^{22, 80}. Rarely the arthritis of rheumatic fever may be so persistent and marked as to simulate acute arthritis deformans⁵³². Generally articular symptoms were transient, chronic arthritis was practically never produced. "Rheumatic fever always discards its articular features eventually" (Kinsella)

Most "growing pains" and leg aches in children are not rheumatic, according to Shapiro who again differentiated between the rheumatic and non-rheumatic variety^{247, 482}.

Heart Statistics on the incidence and type of cardiac disease in the current cases conformed to previous data^{11, 85, 197, 307, 482, 572, 577}. Although the heart is practically always affected, the cardiac damage does not persist in all cases and Derick often noted disappearance of disturbances of conduction time. "The heart is frequently spared in the first attack, rarely in the second, probably never thereafter". Of Banerjea's patients in India 12 per cent had "active carditis," 60 per cent had mitral stenosis, 8 per cent had aortic insufficiency, 12 per cent had mitral stenosis and insufficiency, and in one case (4 per cent) mitral and aortic stenosis and aortic insufficiency were present. According to Carruthers, multiple valvulitis is distinctly less common in India than in the United States. But the percentage of cases of rheumatic carditis with no previous history of rheumatic fever was no greater in the Bombay Deccan than elsewhere. Therefore Carruthers could not agree with McLean (1932) that there is a greater incidence of rheumatic carditis without rheumatic fever in the South.

Some cardiologists state that organic mitral regurgitation is rare and never causes serious disability, and that high grades of mitral disease always involve mitral stenosis. However, according to Dana and Reidy pure mitral regurgitation is not uncommon, occurs in 20 to 50 per cent of all cases of rheumatic mitral valvulitis, and it alone can cause death, uncomplicated by disease of other valves or by pericarditis. Pure mitral stenosis is rarely found at necropsy and its clinical importance is much overemphasized. Contrary to the belief of some, rheumatic fever does not predispose to arteriosclerotic coronary disease in later life, according to Gross and Oppenheimer.

Acute rheumatic myocarditis is one of the rare causes of sudden death. Not preceded by a history of rheumatic fever or carditis, it caused the sudden death of a 59 year old woman in whose heart Mallory found more Aschoff bodies per cu mm than he had ever seen before. Studies on the pathology of valves, valve rings and the auriculoventricular conduction system in rheumatic fever were reported^{196, 215, 216, 217}.

Pericardium Clinical signs of acute pericarditis were noted in 12 per cent of cases,^{11, 80} 14 per cent⁴⁵⁰ and 19 per cent¹³⁸ Other data on rheumatic pericarditis were reported^{188, 117} Rheumatic fever rarely causes significant pericardial effusions, "only an examination candidate revels in paracentesis pericardii" ^{197, 438, 439}

Lungs Rheumatic pneumonia occurred in 7.6 per cent of Ash's 416 rheumatic children, appearing only in those severely affected Bronchopneumonia or lobar pneumonia may occur at any stage of the disease, according to Willius Poynton listed four types of pulmonary complications 1 Massive collapse may occur, usually on the left, sometimes on both sides It is early manifested by intense tubular breathing at the lower angle of the scapula, which then spreads downward When classic it has no other adventitious signs and will appear, disappear, reappear and disappear 2 Bronchopneumonia may appear alone or may complicate massive collapse 3 Pleural effusion may appear and necessitate paracentesis 4 Acute edema of lungs—sharp, bright crepitations commencing in upper lobes—was noted by Poynton only in patients receiving large doses of salicylates Mallory stated, "So far I have no clear conception as to whether there is a rheumatic pneumonia entity I cannot make head or tail of the descriptions" Noted by him were multiple focal areas of hemorrhage through one lung, looking much like infarcts but usually not leading to complete necrosis of lung tissue, also microscopic lesions were seen in some of the very small pulmonary arteries near hemorrhagic foci Histologically the lesions were "about half-way between infarcts and pneumonia in appearance"

Chorea (as a Symptom) Chorea was noted in 5 to 34 per cent of current American cases^{11, 85, 197, 572} but in very few of those seen in India^{22, 80}

Nodules Subcutaneous nodules were noted in 2.4 per cent of Ash's cases, in 8 per cent of Banerjee's cases, but in 37 per cent of the fatal cases of Gibson and Denenholz Not all "fibrous nodules" are actually fibrous some can appear and disappear within three days Rheumatic nodules have three zones an outer one of swollen fibrous tissue containing distended capillaries, a middle one full of leukocytes and mononuclear cells and a central zone of necrosis (Poynton)

Abdominal Symptoms Writers are stressing the fact that abdominal pains may be one of the rheumatic symptoms They occurred in 13 per cent of Ash's 416 cases, in three cases symptoms warranted surgical operation, only acute generalized mesenteric lymphadenitis was found (However in three others intercurrent acute appendicitis was found at operation) Wolffe and Brim reviewed the literature thereon, reported three such cases, and summarized the features of these and other cases

The gastrointestinal inflammation produces recurring spells of abdominal cramps Attacks may be acute or chronic When acute, the cramps may last a few minutes or a few hours The pains are sharp, sometimes about the umbilicus, sometimes generalized, but usually epigastric and not radiating Nausea may be present, occasionally vomiting Abdominal tenderness may or may not be present, rigidity

is absent. An episode is usually over before the next meal and the child generally continues to eat and play. Constipation is generally present, also slight fever, rarely over 101° F. There may be a history of slight nose bleeds or of pains in muscles and joints, or the cramps may be the only subjective rheumatic manifestation. Attacks may recur over a period of six months to several years. If the condition is chronic the patient notes mild attacks of fleeting abdominal pain from time to time without other signs or symptoms except occasionally diarrhea alternating with constipation. Unlike appendicitis, successive attacks become milder.

Laboratory Data (Electrocardiograms, Sedimentation Rates, Blood Counts, Urinary Studies) The practical value of the electrocardiographic Lead IV is "definitely limited" according to Robinow, Katz and Bohning who studied results in normals, in children and in adults with active and inactive rheumatic fever.

Erythrocyte Sedimentation Rate The close relationship between rheumatic activity and altered sedimentation rates received further notice. The test allows accurate observations on the progress of the disease but other conditions which alter the test must be known. According to Payne and Schlesinger the rate is not altered by an uncomplicated common cold or by "chronic" tonsillar infection but is notably altered by acute tonsillitis and influenza. In acute chorea there is no, or only a small, transient, increase of rate. Congestive cardiac failure has a curious effect on the rate, however active the rheumatic process may be, the onset of congestive failure and edema causes the rate to fall from a previous high figure, sometimes to normal. Such a fall in the presence of active disease is a bad prognostic sign. When nodules are present the test has prognostic significance, a fall of the rate heralds their disappearance. "Miniature rheumatic fever" is characterized by slight fever and transient tachycardia. Such a state, precipitated by tonsillitis or respiratory infection, may be subclinical but is indicated by changes in the rate.

To determine the mechanism of production of increased rates Coburn and Kapp studied changes in rate occurring in the three phases of a rheumatic attack: the pharyngitis or respiratory infection, the silent phase, and the phase of attack. In rheumatic patients who did not develop an exacerbation after pharyngitis, sedimentation rates were either not or very slightly and briefly (for 10 to 15 days) altered, but in those in whom pharyngitis precipitated a rheumatic exacerbation the rate suddenly rose to a high level late in the "silent" phase just before "the attack." By varying the concentrations of plasma protein Coburn and Kapp determined that increased rates in acute rheumatism are caused by an increase in plasma fibrinogen and globulin.

Removal of total serum lipoids and crystalloids did not appreciably affect the rate. Dilution of plasma with Ringer's solution slowed the rate as did removal of fibrinogen. Removal of globulin and fibrinogen inhibited rates almost completely. Adding globulin, but especially fibrinogen, increased the rates. The globulin and fibrinogen in blood of rheumatic patients was qualitatively the same as that in normal blood. It was suggested that fibrinogen and globulin are produced by the reticulo-endothelial system.

Blood Counts The behavior of eosinophilic polymorphonuclear leukocytes in rheumatic fever is similar to that seen in other infections. Friedman and Holtz noted that eosinophiles are absent or diminished in number during the height of acute rheumatic polyarthritis and carditis, and reappear during the stage of recovery, so that there is a postinfectious eosinophilia as in other infections. Long continued aneosinophilia and hypo-eosinophilia during acute polyarthritis or during acute or chronic carditis indicate intensely active infection. Recurrent and continuous eosinophilia indicates convalescence.

The sedimentation rate is a more sensitive and practical index of rheumatic activity or inactivity than the Schilling count (Struthers and Bacal, Rogatz). In the acute stage there is a marked shift to the left in the Schilling hemogram, that is, the percentage of immature polymorphonuclear leukocytes rises above 10. As the disease becomes inactive the shift returns to normal with, or often two or more weeks before, the sedimentation rate. Patients should not be allowed up until the sedimentation rate is normal.

Synovial Cytology Sterile fluid from a synovial effusion of one febrile rheumatic patient contained 7200 total cells per cu mm with 92 per cent polymorphonuclears.⁹³

Urine Coproporphyrin in abnormal amounts was found by Kapp and Coburn in the urine of patients with acute rheumatic fever, concurrently with onset of symptoms. Normal amounts were found in the urine of patients with inactive rheumatism. Its appearance bore no relationship to fever, hematuria or therapy, and probably indicated some kind of hepatic damage.

RELATIONSHIP OF RHEUMATIC FEVER TO OTHER DISEASES

To Subacute Bacterial Endocarditis Reports under review contained no new comments on this point. Death from subacute bacterial endocarditis occurred in a few cases.^{455, 482, 572}

To Atrophic Arthritis Most physicians believe that rheumatic fever and atrophic arthritis are not manifestations of the same disease and bear little or no relationship to each other.^{8, 271} In the United States acute atrophic arthritis practically always leaves persistent articular damage, rheumatic fever "always discards its articular features."³⁰⁷ Although Cecil did not regard the two as the same disease he thought they might be related etiologically. Dawson and Tyson considered them closely related, differing in degree rather than in kind. According to them rheumatic fever and atrophic arthritis tend to occur in the same families. Each disease appeared with almost equal frequency (14 and 15 per cent respectively) in the families of 100 patients with atrophic arthritis. They considered the geographic, age and seasonal incidence and the precipitating factors, to be about the same in both. Subcutaneous nodules of "very similar nature" appear in both.

(We do not believe they are similar—Ed.)

However, immunologic differences obtain in rheumatic fever anti-streptolysins are high, streptococcal agglutinins are not, in atrophic arthritis the reverse occurs. Even so hemolytic streptococci may play a rôle in both diseases. But even were both caused by the same agent they could be different diseases, witness the relationship between syphilis and yaws. Although the two diseases may represent different responses to the same or closely related agents, Dawson and Tyson stressed the importance of differentiating them clinically, for each has its own symptoms, therapy and prognosis.

(Too much credence cannot be given statements that both diseases are rare in the tropics. Statistics published elsewhere²⁴⁷ and herein tend to refute this idea. If the differences between the two diseases depend largely on age, one should not so frequently see Still's disease (juvenile atrophic arthritis) in children or an initial attack of classical rheumatic fever in adults more than 40 or 50 years of age—Ed.)

Differential Diagnosis Kinsella and Archer reviewed the usual points which differentiate the disease from Still's disease, acute atrophic arthritis, gonorrheal arthritis and gout. Annually there are reported one or two cases of leukemia simulating acute rheumatism, presenting fever and joint pains. Conybeare reported such a case.

Course and Prognosis "As the heart goes so goes the disease" is a timely but truthful paraphrase. The principal cause of heart failure is not physical strain but continued infection, in particular the prolonged activity of the rheumatic infection, according to Werner. Respiratory infections lowered the cardiac reserve of 50 per cent of Werner's patients with rheumatic carditis but also of the same percentage of those with syphilitic carditis. The rôle of respiratory infections therefore seemed to be nonspecific.

Effect of Pregnancy Pregnancy coincident with heart disease is serious for both mother and child, the maternal mortality is high (3 to 8 per cent), premature birth is frequent. At least 1000 women are said to die annually in the United States from heart disease complicating pregnancy and 90 per cent of the carditis is rheumatic. The maternal mortality in the Toronto General Hospital under such circumstances was 2.3 to 3.4 per cent. Henderson changed the regimen with the result that in a new series of 35 deliveries 46 per cent were spontaneous, 51 per cent were by forceps, 3 per cent only were by cesarean section and sterilization. One patient died from heart failure. Premature birth occurred in seven cases (20 per cent). Once cardiac insufficiency has occurred the maternal mortality is more than doubled, if labor occurs during cardiac failure the mortality is about 50 per cent. Henderson recorded his prenatal regimen, indications for termination of pregnancy and for sterilization, also his management of the various stages of labor.

Recurrences The mechanism underlying relapse is not understood. Poynton and Swift asked: Are they caused by the introduction of fresh infection from some distant focus into susceptible subjects, by some sudden

failure in resistance before the infection is thoroughly destroyed, by some fresh revival of the virulence of the infection which is passing through a phase in its life history? Are they caused by an altered reactivity of tissue so conditioned that slight insults of various types lead to a peculiar mode of response, or by the prolonged residence of some infectious agent in the rheumatic subject, with alternate periods of almost complete immunity and then of diminished resistance?

In 52 per cent of Shapiro's 342 cases of juvenile rheumatism only one attack was experienced, the rest of the patients had recurrences, 54 per cent of them within two years, 17 per cent in the third year, 12 per cent in the fourth year, 3 per cent in the fifth year and 14 per cent thereafter. Until five years have elapsed a patient cannot be too hopeful of escaping a recurrence.

Evidence of Reactivity and Quiescence Ruprecht's criteria of "arrest" included disappearance of subjective signs and symptoms, and normal values for the following: temperature, leukocyte count, Schilling hemogram, nonfilament count and sedimentation rate. Sutton and Dodge gave their criteria for a diagnosis of active carditis.

Bland, Jones and White observed 1000 young patients with rheumatic carditis for 10 years. There was a regression in physical signs in many, a total disappearance of clinical signs of carditis in 83 cases (8.3 per cent).

End Results Twenty-two per cent of Ash's patients with juvenile rheumatism were dead after an average of 7.5 years, and 10 per cent of Shapiro's patients were dead after an average of 6 years of illness. Lesions noted at necropsy were recorded. Banerjee's figures on the mortality of the disease in India agreed with those of Lewis (1933) in England. Relapses occurred in 40 per cent, death occurred within two years in 4 per cent, within 10 years in 24 per cent. Willius' 160 cases, studied until death, included adults, at death 78 per cent had mitral disease, 13 per cent aortic, and 9 per cent both mitral and aortic disease. The first two groups lived an average of 21 years, the third group 16 years after the disease's onset. The disease was rapidly fatal among the Chicago children observed by Gibson and Denenholz, in 40 per cent the first attack of carditis proved fatal. The average age at onset of the disease was 6.3 years, its average duration until death, only 1.4 years. Twenty-seven per cent died within three months of their first rheumatic manifestation.

ETIOLOGY AND PATHOGENESIS OF RHEUMATIC FEVER

Factor of Infection Direct and indirect bacteriologic evidence for the infectious theory were summarized by several (table 1)^{447, 532}

1 *Respiratory Infections* The majority now consider the prodromal respiratory infections to be nonspecific provocatives. Among Shapiro's cases the disease appeared spontaneously in 45 per cent, was preceded by colds in 14 per cent, by a sore throat in 5 per cent, by other factors in 36

TABLE I

Immunologic and Chemical Differences between Rheumatic Fever, Atrophic (Rheumatoid) Arthritis and Hypertrophic (Osteo-) Arthritis *

| Test | In normal persons (or other controls) | In rheumatic fever | In atrophic (rheumatoid) arthritis | In hyper- trophic (osteo-) arthritis | Comment significance of test |
|--|---|--|---|--|---|
| Skin reactions to nucleoproteins of streptococci | Occasionally + (in 20-40 per cent) Occasionally + (in 20 per cent or less) | Generally + (in 75-80 per cent) Occasionally + (in 20 per cent or less) | Generally + (in 75- 95 per cent) Max- imal reactions com- mon Occasionally + Maximal reactions rare | Generally - Occasionally + Generally - | Significance debatable Positive much more frequently to hemolytic than to green streptococci Not strain specific No definite correlation between skin reactions and agglutination test |
| | Rarely + Occa- sionally + in non- rheumatic patients | + in some cases (25 to 50 per cent) | + in high titer (75- 90 per cent) | Practically al- ways - Rarely + | Significance debatable Reactions are to several, not to one, strain No cor- relation between agglutination tests and the duration, extent, or severity of patient's arthritis Presence of such agglutinins may be attributable to nat- ural rather than to acquired or specific immunity |
| Agglutinins to <i>Streptococcus</i> <i>viridans</i> | Rarely + (in about 5 per cent) | Rarely + (in 5-10 per cent) | + in 70 per cent of cases but usually in low titer, occasionally in high titer | Generally - Rarely + | |
| | Generally none or very few Occa- sionally present in nonrheumatic pa- tients with recent tonsillitis | In about 60 per cent of active cases + In quiescent cases, generally "nega- tive" | + in 80 per cent of cases (group, not strain, specific) | Rarely + (in 10-20 per cent) | Close approximation, but not an abso- lute agreement, between precipitin and agglutination reactions In rheumatic fever no constant relationship between severity of symptoms and presence of precipitins Precipitin reaction (to hemolytic streptococci) frequently + in various types of arthritis, even gonorrheal |
| Precipitin reactions to fractions of hemolytic streptococci | | | | | |

* Figures given are from the recent literature Normal standards in some instances not yet finally established, contradictory results are frequently noted

TABLE I—Continued

| Test | In normal persons (or other controls) | In rheumatic fever | In atrophic (rheumatoid) arthritis | In hyper- trophic (osteo-) arthritis | Comment significance of test |
|--|--|--|--|--|---|
| Antifibrinolysins (to hemolytic streptococci) | Present in small amounts Present in certain amounts in those without evidence of recent hemolytic streptococcal infections Much increased in erysipelas and other acute hemolytic streptococcal infections | Much increased in 60-70 per cent | Generally not present Occasionally present in cases of early acute arthritis Rarely present in chronic cases | | Antifibrinolysins and antistreptolysins are indexes of recent acute hemolytic streptococcal infection Their presence should not be expected in chronic disease |
| Antistreptohemolysins "antistreptolysins" "antihemolysins" "anhemolysins" | Usually up to 50-100 units Rarely over 150 units Occasionally up to 200-300 units | In about 80-85 per cent of active cases increased markedly (average 500 units) In quiescent cases may not be increased | Only increased (over 150 units) in about 10-20 per cent of cases Later generally not increased | Normal | Significance of antistreptolysins debatable, some say they may be increased in patients with respiratory infections from other than hemolytic streptococci No relation between antistreptolysin titer and agglutination or skin reactions |
| Streptococcal Complement-fixation test | Sometimes + even in pregnancy and tuberculosiis | In active cases sometimes + In quiescent cases only occasionally + | Usually — according to some, usually + according to others | | Significance very debatable Patients may show complement fixation, not only to several strains of streptococci, but also to staphylococci and colon bacilli |
| Sedimentation rate | Generally below 15 mm (in 1 hour) | Markedly increased May return to normal in cases of congestive heart failure | Almost always increased generally over 30 mm (1 hour) | Rarely over 20 mm (1 hour) | |

TABLE I—Continued

| Test | In normal persons (or other controls) | In rheumatic fever | In atrophic (rheumatoid) arthritis | In hyper- trophic (osteo-) arthritis | Comment significance of test |
|------------------------|--|--------------------|--|--|---|
| Total blood proteins | 6-8 gm per 100 c c | | Normal | Normal | |
| Plasma fibrinogen | 300-600 mg per 100 c c | | Increased | Normal | |
| Serum globulin | 1 2-2 3 gm per 100 c c | Increased | Increased | Normal | Tends to rise in infectious diseases |
| Serum albumin | 4 6-6 7 gm per 100 c c | Decreased | Decreased | Normal, or slightly de- creased | |
| Albumin-globulin ratio | 1 5 1 to 3 1 | | Frequently below 1 Tends to become nor- mal as patient re- covers | Normal | |
| Serum calcium | 9-11 mg per 100 c c | | Normal | Tends to be slightly de- creased | |
| Plasma cholesterol | 160-230 mg per 100 c c | | Tends to be decreased | Tends to be in- creased | Tends to fall in infectious diseases, rise in "metabolic diseases" |

per cent About 50 per cent of the patients of Gibson and Denenholz noted no prodromal respiratory infections According to Swift, severe pharyngitis or tonsillitis of apparent hemolytic streptococcal origin produces rheumatic relapses in 50 to 60 per cent of previously rheumatic subjects but produces rheumatic symptoms in less than 10 per cent of nonrheumatic subjects The disease has been precipitated by incasles, other exanthems, antismallpox vaccination, injuries, surgical operations, foreign-protein (typhoid) reactions

2 Blood Cultures Blood cultures made by McEwen, Alexander and Bunim on 90 patients with febrile rheumatic polyarthritides were sterile in 83 per cent of cases, positive in 17 per cent, hemolytic streptococci were found in 3 per cent, green-producing streptococci in 13 per cent, indifferent streptococci in 1 per cent Comparing results with those in normal and pathologic controls, they concluded that streptococci cannot be isolated from the blood in rheumatic fever (or in atrophic or other arthritides) more frequently than in miscellaneous diseases Streptococci recovered in rheumatic fever did not differ from those in atrophic arthritis Organisms recovered were probably of no etiologic significance If large quantities of blood and suitable methods are used, streptococci occasionally can be isolated from the blood even of normal persons, but more frequently from those whose resistance is lowered by chronic illness Meyer and Ryan cultured the blood of normal and of rheumatic children, using Kendall's medium, a modification of Clawson's method, and serial transfer technic Insignificant bacteria, mostly diphtheroids, were occasionally obtained from patients and controls All specimens would have been considered sterile by usual methods

Cecil does not believe that the bacteria previously recovered by him were contaminants, too many workers have found them in blood, but their significance is admittedly undetermined Poynton warned that results of cultures of tissues and exudates must be interpreted carefully Unlike suppurative processes that may burst into joints, rheumatic processes do not pour streptococci into fluids As one is not surprised by negative cultures in gonorrheal or tuberculous arthritis, so one should anticipate negative cultures in rheumatic fever

3 Skin Tests Positive skin reactions to hemolytic streptococci were noted by Wasson in 79 per cent of 137 ambulatory rheumatic children, in 29 per cent of nonrheumatic controls There was no relation between the intensity of the skin reaction and the degree of carditis The frequency of positive tests increased with the children's age Retesting showed considerable variability in skin tests on the same patient, due to differences in their general and rheumatic condition

Goldie and Griffiths noted positive skin reactions to hemolytic (but not to green-producing) streptococci three times as often in rheumatic patients as in controls Tests were positive in 77 per cent of 85 cases of rheumatic fever (and in 24 per cent of controls) tested with a concentrated solution of hemolytic streptococci, in 34 per cent of 154 cases (but in no controls)

tested with a less concentrated solution. However, skin tests were generally negative in patients with severely progressive rheumatic fever (as patients with miliary tuberculosis may have negative tuberculin tests). Tests with green-producing streptococci were positive in only 27 per cent of 60 rheumatic patients (and in 24 per cent of controls) with a concentrated solution, and in 3 per cent each of 154 rheumatic cases and 30 controls with a less concentrated solution.

4 *Streptococcal Agglutinins* Positive agglutination tests with hemolytic streptococci (titer 1 to 20 or over) were found by McEwen, Alexander and Bunim in none of 35 normal controls, in only 5 of 71 patients with rheumatic fever (titer 1 to 20 in one, 1 to 40 in two, 1 to 80 in three). Thus these workers did not confirm Coburn and Pauli's observation (1932) that serum of most patients with acute rheumatic fever agglutinated hemolytic streptococci to a titer of 1:10 to 1:40. Goldie and Griffith found agglutinins to hemolytic streptococci in a titer of 1:100 in 80 per cent of rheumatic fever patients, in 10 per cent of controls, agglutinins to green-producing streptococci in a titer of 1:100 in only 6 per cent of rheumatic cases, in 5 per cent of controls.

5 *Antifibrinolysins* Patients convalescing from diseases due to hemolytic streptococci generally possess antifibrinolysins, that is, the fibrin in their sera is markedly or completely resistant to fibrinolysis, or liquefaction of blood clot, by cultures of hemolytic streptococci. Confirming the work of others^{245, 246, 247} Stuart-Harris noted antifibrinolysins in the blood of patients with rheumatic fever (but not with atrophic arthritis) particularly during the acute stage or after intercurrent streptococcal infection during convalescence from activity. Thus he considered rheumatic fever (but not atrophic arthritis) related to hemolytic streptococcal infection. The findings of McEwen, Alexander and Bunim were similar, complete resistance to dissolution being noted in 59 per cent, marked resistance in 14 per cent, of 29 patients with rheumatic fever.

6 *Hemolytic Streptococcal Precipitation Tests* Antigenically hemolytic streptococci are complex mosaics containing, among other fractions, a "nucleoprotein" (P fraction) which is not specific as it gives cross precipitation with other gram-positive cocci, a group-specific carbohydrate (C fraction), and type-specific protein and carbohydrate fractions (M and S fractions). Hemolytic streptococci are known to induce the formation, not only of antistreptolysins and antifibrinolysins, but also of two other antibodies, anti-C precipitins and anti-P precipitins. These four antibodies have been demonstrated in the serum of patients with various streptococcal infections. Because they have also been found by some workers in a high proportion of patients with rheumatic fever it has been suggested that there is a close connection between streptococcal infection and this disease. McEwen, Alexander and Bunim, and Chasis and McEwen noted precipitin reactions to crude "C" extracts (fractions) in 56 per cent of 39 patients with rheumatic fever but also in a fairly high percentage of patients with

other articular diseases and in 24 per cent of normal controls. Highly positive reactions were noted equally in those with rheumatic fever or with atrophic arthritis, less frequently in controls. The test therefore was of no differentiating value, an opinion concurred in by Race.

Swift and Hodge studied the development of type-specific anti-M precipitins in two groups of patients suffering with hemolytic streptococcal infections. Most of the patients in group I, none of whom developed rheumatic fever, showed relatively strong type-specific reactions in their serum within four to five weeks. Those in group II all developed rheumatic fever, some had similar strong antibodies early, but most rheumatic patients from whom hemolytic streptococci were cultured in significant numbers from various foci, did not show strong anti-M precipitins until distinctly later than the nonrheumatic group. Swift has repeatedly been unable to show a constant relationship between the severity of symptoms of patients with rheumatic fever and the presence of precipitins against either the "C" (carbohydrate) or the "P" (nucleoprotein) fractions of group A hemolytic streptococci.

7 *Antistreptolysins* ("Antihemolysins" "Anhemolysins") The upper limit of normal was regarded by earlier workers to be 50 units of anti-streptolysin, by later workers to be 150 units^{245, 246, 247}. The establishment of the new level made the test more specific but at the cost of reporting "normal values" in 24 to 30 per cent of cases of rheumatic fever, with titers between 50 and 150. Race believes the upper normal level should be re-established at 50 units. Eighty per cent of 51 rheumatic fever patients (but only 3 per cent of 37 normal controls and 12 per cent of patients with atrophic arthritis) showed 150 or more units of antistreptolysin, according to McEwen and colleagues. However, the titer did not rise above 25 units in one unquestionable case studied over two months. Goldie and Griffiths noted "abnormal values" (over 50 units) in 100 per cent of 40 cases of "rheumatic fever with chorea," in 88 per cent of 154 cases of subacute rheumatism, in 20 to 27 per cent of two sets of controls. Values of 100 + units were found in 92 per cent, 58 per cent and 3 to 8 per cent respectively, 200 + units in 80 per cent, 35 per cent and 0 to 2 per cent respectively. Longcope regarded 100 units as the limit of normality. The antistreptolysin titer was above 100 units in 85 per cent of his cases of acute rheumatic fever, in 86 per cent of cases of chorea, in 80 per cent of cases of erythema multiforme and nodosum, in 28 per cent of cases of "chronic inactive rheumatic heart disease," in 46 per cent of cases of atrophic arthritis. It was over 200 units in 51 per cent, 50 per cent, 60 per cent, 0 per cent and 18 per cent of these same groups respectively. Contrary to the experience of Coburn and Pauli (1935), in Longcope's series the height of the titers did not parallel the severity or duration of acute attacks of rheumatic fever. High titers in this disease should be regarded as the result of a recent hemolytic streptococcal infection but "cannot be used as evidence that [rheumatic fever] is caused by hemolytic streptococci."

Correlation and Interpretation of Immunologic Data The significance

of these data is incompletely understood (table 1) Little has occurred to change the interpretation of the main features as given in the third review Space does not permit the inclusion of reported explanations of the conflicting data and reference must be made to the reports cited Coburn's correlation still seems the clearest, whether correct or not it is the most positively stated It seems to do much to explain the basis for the conflicting opinions (for example, that of Coburn and Wilson) reported in previous reviews It attempts to show why some pharyngeal infections never produce initial or subsequent rheumatic attacks, why some hemolytic streptococcal infections sometimes do and sometimes do not (even in rheumatic subjects) produce attacks, and why rheumatic attacks are generally but not always precipitated in susceptible individuals with the production of antistreptolysins

To clarify the mechanism of its production one must divide the rheumatic process into its three clinical phases which, although symptomatically distinct, are interdependent stages of a specific set of immunologic reactions Each phase must be considered separately, yet sequentially The first phase, that of acute upper respiratory tract infection, lasts only a few days But in this phase are set in motion factors which may or may not eventuate in the rheumatic explosion The second phase follows immediately after the respiratory infection, is characterized by a complete absence of clinical symptoms and signs, and lasts from a few days to about six weeks, generally one to two weeks Although this phase is symptomless it is crucial, for during it, processes initiated in the first phase come to maturity, if they mature in one way, normally as they usually do, a rheumatic attack does not materialize, but if they mature in another way, abnormally, a rheumatic attack of variable severity results The third phase begins with the onset of rheumatic manifestations and varies widely in the duration and intensity of its symptoms

The hemolytic streptococcal infection (pharyngitis) of phase one is nonspecific in at least certain ways, the rheumatic patient is no more or less susceptible to it than the nonrheumatic patient The clinical characteristics of the pharyngitis are the same in the rheumatic and the nonrheumatic, the upper respiratory tract of the rheumatic patient may be infected with the same strains of hemolytic streptococci as that of the nonrheumatic, and the pharyngeal infection has the same variable persistency in the nonrheumatic as in the rheumatic patient Why then does one patient get acute rheumatism and the other not? A crucial difference lies in the type of immune response which the infection generates, furthermore, the chief difference in type is not just a difference in the content of the immune response but in the speed of its development If an immune reaction to the phase-one infection fails to develop (as it may in either the rheumatic or nonrheumatic patient) or if it develops in the second or silent phase, with normal promptness, no rheumatism results in the normal person or even in one previously rheumatic, and the third phase never materializes But if an immune reaction, engendered by phase one, develops tardily in phase two, with abnormal slowness, then rheumatic fever results The basis of this concept follows

The potent types of pharyngitis (as far as the production of rheumatic fever is concerned) are commonly due to hemolytic streptococci, Lancefield group A As they pertain to rheumatic fever they are group but not strain specific These hemolytic streptococci produce two or more soluble antigens (soluble bacterial derivatives or exotoxins) and at least three other antigens (intracellular bacterial derivatives or endotoxins) The two well-recognized soluble antigens are (1) an erythrogenic toxin, probably capable of damaging vascular endothelium and against which the

body generally forms neutralizing antibodies which cause the patient to be "Dick-negative," and (2) streptolysin which the body attacks by the production of anti-streptolysins—antibodies which are specific for hemolytic streptococci, probably group specific, which are quantitatively measurable by titration and which are recognized as bona fide evidences of recent hemolytic streptococcal infection

The three other recognized antigens (intracellular bacterial derivatives) produced by hemolytic streptococci are (1) a type-specific protein, called M-substance or M-extract, against which the body during a rheumatic attack forms "precipitins to M-substance" which can be detected qualitatively in serum, (2) a nucleoprotein called P-substance, against which the patient's body frequently develops "precipitins to P-substance," the presence of which is demonstrated by positive skin reactions to hemolytic streptococcal nucleoprotein, and (3) a group-specific carbohydrate or C-substance, precipitins to which the patient's body develops and delivers to serum

Still another protective substance found in the blood of patients with rheumatic fever or with definite hemolytic streptococcal infections is antifibrinolysin

The relative importance of these antigenic substances and what pathologic reactions they induce or could induce in the body were they not neutralized by antibodies has not been fully determined. It appears, as one might expect, that erythrogenic toxin and streptolysin are released at the onset of infection whereas the M-substance and nucleoprotein P-substance are liberated after the disintegration of bacterial cells. According to Coburn the antistreptolysin curve (its quantity and speed of development) shows the patient's response to infection. He feels that an understanding of the abnormal response may help to elucidate the mechanism of an attack

The silent phase two varies considerably in length but its duration appears to coincide with the time required for the appearance of the antistreptolysin response in rheumatic patients. Coburn noted previously that in a group of rheumatic subjects infected with a single strain of hemolytic streptococcus those that developed acute rheumatism developed an antistreptolysin response, while those who failed to make this response escaped an attack. He noted that a rheumatic patient who contracts a series of hemolytic streptococcal infections develops acute rheumatism only when the infection is followed by a rise in antistreptolysin titer. In the absence of an antistreptolysin response there was no rheumatic attack. He then studied the comparative alterations in the erythrocyte sedimentation rate and the antistreptolysin titer in 100 patients with rheumatic carditis in relation to different stages of phase three

At the onset of symptoms the sedimentation rate and antistreptolysin titer both rise, at the height of the attack the rate is at its maximum but the titers still rise. When symptoms begin to subside the rate is still at its maximum, the titer is either at its maximum or still continues to rise. As symptoms continue to subside the rate falls but there is a lag in the fall of the titer, the titer may stay at its maximum

the initial symptoms appeared with the appearance of the antibody but the curve of subsequent symptoms did not parallel the antibody titer

After different hemolytic streptococcal infections the time when the maximum concentration of antistreptolysins occurs varies widely. In acute rheumatism maximum titers rarely occur within five weeks, in protracted cases they are not usually reached until several months after the hemolytic streptococcal pharyngitis. This is in sharp contrast to what obtains in erysipelas, for example, where the peak-titer is reached within 20 days after the onset of infection. Coburn found that the clinical character of the rheumatic attack varied with the shape of the antistreptolysin curve. The sooner a patient developed a maximal titer, the sooner he recovered. In other words those curves which approached normal responses (an early rise and fall) were

associated with short or mild attacks. In contrast, those characterized by an abnormally slow rise were associated with a prolonged severe carditis. Apparently then the crucial characteristic of the rheumatic candidate may be a delay in his immune response to hemolytic streptococci. As stated, following a hemolytic streptococcal infection a nonrheumatic person either (rarely) develops no rise in antistreptolysins or generally develops a prompt response with a maximal antistreptolysin titer within 20 days. If the rheumatic subject makes either of these two responses he escapes an attack. That is, if there is no antistreptolysin response there is no attack, or if the increased antistreptolysins appear promptly and reach their maximum early and normally (within 20 days) there is no attack. But if, as frequently happens, the rheumatic patient develops an intense delayed antistreptolysin response a week or more after the normal response should have occurred, acute rheumatism develops.

In conclusion, Coburn stated that until now there has been no evidence whether the antistreptolysin curves seen in rheumatic fever were normal responses to hemolytic streptococcus infection or not. His data would indicate that the immune responses of the rheumatic patient differ from the normal chiefly in that they are delayed. This being so it may be assumed that the rheumatic subject who develops an attack handles the products of hemolytic streptococci peculiarly, involving a delay in the final elimination of hemolytic streptococcal products from the body. Why such a delay occurs or how it is associated with the development of the disease is undetermined.

Factor of Bacterial Allergy Poynton's simple interpretation of what is presumably meant by bacterial allergy seems worthy of inclusion.

Assume that an infected focus is a streptococcal depot more or less constantly pouring into the circulation the body-protein of streptococci, which acts as a foreign body circulating in the human system. Such foreign substances stimulate the production of specific antibodies, hence are called "antigens." Antigens arising in a focus of infection and circulating in the body will stimulate certain tissue cells to produce antibody and in doing so this will sensitize these cells. If the response to antibody is prompt and abundant a surplus of this antibody will appear in the circulation and from now on antigen escaping from the focus of infection will meet this surplus antibody in the blood stream and be neutralized there, consequently will not reach the tissue cells. But should the production of antibody be deficient and there be no surplus in the blood stream, but the whole amount be kept back in the producing cells, a different situation arises. The continuous supply of antigen from the focus of infection has then no antibody meeting it in the blood stream, and hence will not be neutralized there but will once more reach the cells which, however, now contain a store of antibody. The antigen then combines with the antibody in the cells and this clash of antigen and antibody will irritate those cells. Thus this antigen, which was formerly innocuous to the cells when they contained no antibody, now acts as a cellular poison to them because they contain antibody. Such reactions are called hypersensitiveness or allergy. Under the theory of bacteremia or bacterial toxemia as the cause of rheumatism (which Poynton espouses) it is supposed that streptococci by their presence or by their toxins produce the local articular (and other) lesions by local infections, but the theory of bacterial allergy assumes that the antigens (streptococcal products) are not toxic per se unless or until they clash with antibody in the tissue cells.

Swift's concept of rheumatic fever as a manifestation of bacterial allergy

is well known, has been discussed herein before^{240, 246, 247} and needs no detailed repetition. He considered it obvious that rheumatic fever patients are unusually hypersensitive to many different injurious agents, but mostly to streptococci. Although all the possible relationships between hyperergy and rheumatism have not been explored the concept clarifies much that seems inexplicable otherwise. However, Schlesinger found it difficult to explain valvular vegetations and pericardial "bread and butter" exudate purely on an allergic basis. He regarded those who believe allergy to be the fundamental cause of rheumatism "still somewhat hazy in their reasoning." "A much stronger case will have to be made out for allergy before such striking, marked changes are regarded as anything but the inflammatory result of an infective agent at the site."

Virus Theory The isolation of "virus bodies" from exudates of rheumatic patients was recently reported but the disease had not been experimentally reproduced²⁴⁷. Swift raised two objections to the theory. 1 Filtrable viruses apparently do not produce fibrinoid degeneration, a basic pathologic feature of the disease. 2 No virus for rheumatic fever has been definitely discovered. The results of Swift's 15 years' search for such a virus were essentially negative, methods by which he sought them were briefly summarized. Either virus was not present in material used or the various animal species tested were not susceptible. Nevertheless a possible symbiotic relationship between virus and bacteria must be borne in mind. Possibly an allergic state makes the tissues susceptible to a hypothetical specific virus, or vice versa, possibly such a virus may cause an allergic state so that bacterial infection or other traumatic insult sets off an acute attack.

Synergism of Infection and Vitamin C Deficiency Rinehart restated his concept that the disease may be due to the combined influence of vitamin C deficiency and infection (as discussed previously in Reviews 2 and 3). It is based on the experimental production of subcutaneous nodules, cardiac and articular lesions, "comparable to those of rheumatic fever" (and to a certain extent of atrophic arthritis), in guinea-pigs subjected to the influence of both infection and vitamin deficiency, but not in those subjected to either factor alone. He further noted a borderline or frank vitamin C deficiency in the diets of most rheumatic children. Plasma ascorbic acid levels usually parallel the vitamin C intake²¹⁸. Rinehart, Greenberg and Christie noted a lowering of plasma ascorbic acid in almost all of 21 patients with acute rheumatic fever, in many with the disease quiescent. It has not been determined whether the reduction was due to inadequate intake, or to the anorexia, digestive disorders or depletion by the disease itself.

Various cardiac and articular lesions were produced by Schultz in guinea-pigs subjected to infection and experimental scurvy, alone and in combination. Infected scorbutic animals developed focal interstitial valvulitis, fibrinoid degeneration, occasionally focal, nonpurulent myocarditis. Non-infected scorbutic animals developed lesions similar but of less extent. In

either case Schultz regarded them as only slightly resembling those of rheumatic fever. No verrucous endocarditis was seen and the myocardial lesions were few and did not closely resemble Aschoff bodies. Scorbutic changes were noted in and around joints but were not enhanced in the infected animals. In 8 of 13 patients with rheumatic fever, some degree of ascorbic acid deficiency was noted by Sendroy and Schultz. It was ascribed to poor diets in two instances, to vomiting or incomplete absorption in six cases. They concluded that ascorbic acid deficiency is not specific for rheumatic fever, is probably incidental in this disease, and did not seem to be a predisposing factor.

Conclusions on Etiology Although interested in the conjecture that the disease represents a symbiosis between virus and streptococci, Schlesinger did not regard any current theory with satisfaction. The so-called specific streptococci of Poynton and Paine, Birkhaug and Small do not produce lesions characteristic of the human disease and are found in the throats of nonrheumatic persons. Hemolytic streptococci are not present in the throats of normal persons, but some patients severely infected therewith do not get rheumatic fever and the disease is obviously not precipitated by a specific strain. Reviewing his own work and that which has followed it, Poynton concluded that the cause of the disease is a diplostreptococcus of a special type (which on various media appears as a streptococcus, or even a staphylococcus), a constitution of a special type, a focus of infection, an invasion of the system by streptococci and the formation of foci of a peculiar type within the body in "the connective tissue skeleton" and the development of poisons injuring the "noble tissues," heart, brain and so forth. "The future must decide whether [streptococci] are gangsters, or the accessories of gangsters, or just the watching crowd always in the way and never doing anything themselves, a rôle not peculiar to streptococci."

TREATMENT OF RHEUMATIC FEVER

Treatment remains essentially as before. Its general principles were reviewed by many^{527, 532}

Bed Rest This should be continued after all symptoms have disappeared, for at least two weeks in those without evidence of carditis, for months (6 or more), not weeks, in those who develop carditis^{461, 577}. It should be continued until the patient has gone six to eight weeks with no signs or symptoms of disease and with a normal sleeping pulse rate (well below 90 per minute)²². Adequate rest involves the use of appropriate sedatives.

Salicylates Salicylates are still considered "extremely useful"^{22, 461}. Some believe they shorten the disease and minimize danger to the heart³⁵³. Others believe they do not affect the proliferative reactions, for which drugs are of little value. But the action of salicylates on the exudative features of the disease is almost specific and diagnostic, affecting other types of fever

or effusion in no comparable manner¹³⁸ One must not conclude that the disease is necessarily inactive when fever is controlled by salicylates, Poynton disapproved "desperate efforts" to lower temperatures thereby Some used large,³⁵³ others used smaller doses⁵⁶ Kaisei concluded that acetylsalicylic acid, combined with magnesium oxide, was superior to salicylates alone in controlling joint pains and chorea and, in preventing recurrences, but not in relieving carditis

Other Drugs Poynton preferred tolysin to salicylates Pyramidon was used by some,⁵⁶ avoided by others for fear of granulocytopenia⁷ Some considered digitalis valuable in congestive failure, useless in controlling tachycardia²² Although it occasionally slows the pulse and improves circulation its results are disappointing unless fibrillation is present¹³⁸

Removal of Tonsils and Other Foci Kaiser summarized the effect of tonsillectomy on 48,000 rheumatic children Tonsillectomized children are less likely to develop subsequent rheumatic fever and carditis, but as likely to develop muscular rheumatism and chorea as those who retain their tonsils However, the incidence of recurrent attacks of rheumatic fever is not influenced by tonsillectomy done either before or after an initial attack Tonsillectomy does influence end-results of the disease The mortality was nearly twice as high among children in possession of their tonsils at the initial attack as among those tonsillectomized before their initial attack "Tonsillectomy is justified in practically every rheumatic child until other factors that influence this disease are better understood"

When performed, tonsillectomy should be done after the acute phase of the disease,⁴⁵⁵ and only when there is evidence of diseased tonsils¹³⁸ Even then it should be considered a major operation with preoperative and postoperative bed rest^{353, 521} The danger of exacerbations after tonsillectomy can be "greatly lessened" by the daily administration of acetylsalicylic acid for one month after tonsillectomy⁷ Wallace and Smith found no evidence that the very early removal of tonsils of children (before the age of five years) protected them against rheumatic fever

Vaccines The use of streptococcal vaccines was "unsound," according to some,⁷ useless according to others Stroud gave vaccine intravenously to children for three years those vaccinated did no better than the unvaccinated

Serum Hoping that the blood of patients recovered from rheumatic fever might contain enough antibodies to help those with active disease, Archer treated four patients intrathecally with small doses of convalescents' serum Results were "suggestive enough" to warrant further clinical trial

Transfusions Weiss noted "satisfactory results" from the use of multiple small (150 to 250 c c) citrate transfusions Results in one case were reported, others were to be reported later

Vitamin C Many of the rheumatic children studied by Rinehart were on a diet low or frankly deficient in vitamin C Preliminary results from

diets rich in vitamin C were "encouraging" Many patients gained weight, a number suffered respiratory infections without rheumatic exacerbations However, the oral administration by Schultz of 100 mg of ascorbic acid (redoxon) daily for several months to 28 rheumatic patients did not lower the incidence of subsequent rheumatic activity as compared to a control group treated by lactose Another group of 17 patients with active rheumatic fever were given 250 mg of ascorbic acid daily by mouth or intravenously for from one to five (average 2.5) months, some were also given 200 c c orange juice daily The disease was not affected thereby Wright also was unable to affect the course of the disease by giving cevitic acid (ascorbic acid, crystalline vitamin C) in doses as large as 1000 to 2000 mg intravenously daily Rhinehart does not believe that lack of response to vitamin C therapy necessarily disproves the etiologic importance of vitamin C deficiency, the latter may be only one factor in preparing the soil for infection But Wright believed that the disease, if related to a deficiency, should be ameliorated to some degree by such large doses

Fever Therapy The chorea of 16 children with active carditis was being treated with foreign-protein fever by Sutton and Dodge Nine of the children lost signs of activity during the course of treatment, in the rest the carditis was clinically inactive within seven to ten days thereafter Subsequently, seven patients with subacute carditis without chorea were treated with artificial fever (two to five hours, at 105° to 106° F for one or two sessions), soon thereafter signs of active carditis disappeared or notably diminished Further investigation seemed warranted

Additional Therapy for the Heart Severe angina pectoris may occur in young people with rheumatic carditis Attacks may appear at night, recumbency seems to precipitate them Good results (better than in arteriosclerotic angina) were obtained by Bland and White in four such cases by paravertebral injections of procaine and 95 per cent alcohol, blocking sympathetic rami of the first four dorsal roots Left-sided injections were usually effective, bilateral injections were occasionally made

Institutional Care, Climate Active subclinical carditis may long persist, sometimes even with a normal sedimentation rate (Sutton) Therefore prolonged observation and care are required before and after patients are returned to their homes, to activity and to school life Rheumatologists and cardiologists are heartily approving convalescent and rest homes, sanatoria for the prolonged supervision of convalescence, and schools for "cardiac cripples" as an important intermediary between hospital care and an active routine which, begun too early, may provoke exacerbations^{439, 455, 465} By such "rheumatism schemes" as that in Cardiff⁴⁹³ or that of the London County Council cooperating with voluntary hospitals and rest homes, much has been done to "commute the sentence of death" from rheumatic fever The established institutions and "cardiac schools," however, cannot deal with more than a fraction of the cases, and it is impossible to send most patients for a prolonged stay in the tropics^{133, 332}

Prophylaxis The multiplication of convalescent homes, special clinics, and rheumatism supervisory centers may prevent more deaths, but not the disease McSweeney called it "philanthropy not prophylaxis" Current methods for prophylaxis are inadequate as the incidence of the disease shows There is therefore great need for the institution of an active, sustained crusade against the disease, following general principles similar to those so successfully employed against tuberculosis This involves better personal and social hygiene, more effective child welfare schemes and school medical service under which physicians and nurses exercise closer supervision over children's health Rheumatic fever should be a notifiable disease, notification would permit subsequent sociologic and epidemiologic studies of the greatest importance (Ritchie)

SYDENHAM'S CHOREA

Chorea accompanied rheumatic fever in 5 to 34 per cent of recent cases, it was an initial symptom in many (21 to 28 per cent) ^{11, 85, 197, 572} It was rare in India ⁸⁰ Statistics indicated that chorea per se is a mild manifestation of rheumatism but may be associated with severe, even fatal, carditis ^{11, 197}

Most writers agreed that chorea is most commonly caused by rheumatic fever but can be precipitated by other factors fright, chilling, emotional shock, fatigue Smith and Markey stressed the emotional factor, Guttmann noted its incidence with psychoses Poynton regarded rheumatism the main, fright a rare, cause, fewer London children had chorea the year of the terrifying war-bombings than the following year

In acute chorea Payne and Schlesinger noted either no rise of the sedimentation rate (in 44 per cent of cases) or only a slight transient rise (in 56 per cent) It was no index of choreic severity or of impending carditis Indeed rates were often very low Struthers and Bacal noted normal sedimentation rates and Schilling counts

Treatment Large doses of phenobarbital controlled a case of severe chorea of 4 5 months' duration in a child, aged 11, seen by Litchfield, Gillman, Harris and Cohen During four weeks' treatment the dose was gradually raised from 1 5 to 22 grains daily without toxicity Smith considered nirvanol therapy drastic, sometimes dangerous because of its effect on bone marrow

Several reports testified to the superiority of fever therapy over other methods Of 50 patients treated by Weisman and Leslie with fever reactions from typhoid vaccine 46 became symptom free, two improved, two did not, only five patients had recurrences within three years Treatments were given daily for seven to eight days, omitted two to four days, then continued as necessary Generally eight or nine fever reactions (to 104° or 105°, occasionally 106° or 107° F) were given, the greater the fever, the better the results Those with active carditis seemed to do as well if not

better than others. Results of similar treatments were excellent in six, poor in two, of eight cases seen by Litchfield and his colleagues. Fever reactions to 104° or 105° F were induced daily for 7 to 12 days.

The results of Sutton and Dodge were even more striking. Among 150 patients treated by orthodox methods the average duration of chorea after therapy was begun was 43 (10 to 180) days. Of 150 patients treated with triple typhoid vaccine symptoms averaged only 9 (2 to 47) days after treatment. Vaccine injections were given daily, with an occasional rest day, until chorea stopped. The number of injections averaged five in mild cases, six in moderate cases, nine in severe cases (maximum 18). Because typhoid vaccine fever reactions are not as controllable as artificial fever, 16 other patients were treated with the latter (radiant energy). Results from only one or two artificial fever sessions were as good as those from several vaccine-fevers. Subacute carditis was not a contraindication, indeed it seemed to be relieved.

Excellent results from artificial fever were noted by others. All of 13 patients treated by Barnacle, Ewalt and Ebaugh were "cured." No recurrences were noted within one year. Six cases of "most severe" chorea of two weeks to 10 months' duration were slowly but completely stopped by similar treatments given by Metz. Symptoms disappeared within two to four weeks. Neymann, Blatt and Osborne also noted excellent results from fever (electro-magnetic induction) in 25 cases, nine very severe, six moderate, ten mild. From two to ten (áv four) treatments were given, two per week. Recurrences occurred in 12 per cent. Complications were a heat convulsion in one case, transient albuminuria and hematuria in one case.

CHRONIC ARTHRITIS

General Remarks on the Relationships and Distinctions between the Two Great Types. Those who espouse the "unitarian idea" consider atrophic and hypertrophic arthritis varieties of one disease, differences being due chiefly to the factor of age, physiologic rather than calendar. To them atrophic arthritis represents the reaction of physiologically young tissues against an insult, hypertrophic arthritis is the reaction of physiologically aging tissues against the same insult. Others, more equivocal, believe the two great types are very closely related etiologically, but are probably different diseases. Some believe that both types of chronic arthritis are often the result of similar factors.^{279, 380} Most rheumatologists, however, stress the distinctions between the two types and consider them totally unrelated diseases, "sharing little but a common battleground."^{165, 223, 388} Citing the manifold constitutional, clinical, cytologic, chemical, immunologic, pathologic, roentgenographic and prognostic differences between them they would conclude with Boots: "There would now seem to be no further excuse to look upon these cases as examples of a single disease." The frequency of patients with mixed (clinical, not just radiologic) types, who demonstrate

both atrophic and hypertrophic arthritis in different or even in the same joint, does not confuse those who realize that every young or middle-aged patient with atrophic arthritis will, if he lives long enough, develop hypertrophic arthritis, since the latter is a histologic (although not necessarily a symptom-producing) inevitability to all persons over 50 or 60 years of age. Then too, patients over 50 years of age with hypertrophic arthritis are not immune to atrophic arthritis which even the elderly may develop independently of their coincidental hypertrophic arthritis.

Clinical and Pathologic Distinctions The familiar clinical and pathologic distinctions between atrophic and hypertrophic arthritis were again reviewed ^{48, 194, 195, 200, 300}

Cytologic, Chemical and Immunologic Differences These were again summarized ^{83, 130, 243} (table 1)

Roentgenographic Differentiation According to S. G. Scott clinical diagnoses of the chronic arthritides can be made with considerable accuracy from roentgenograms alone, particularly of hands. Others^{4, 172, 177, 504, 535} regard roentgenographic differences as highly suggestive but not pathognomonic. They believe that a final clinical diagnosis cannot be based on roentgenograms alone, features of the latter must be correlated with clinical and biochemical findings. Although osteophytes are much commoner in hypertrophic arthritis, they are frequently seen in late atrophic arthritis, especially in weight bearing joints, or they may occur in almost any infectious type of suppurative or nonsuppurative arthritis. A radiologist, noting these osteophytes and having no knowledge of the clinical features, will often classify such a case as hypertrophic arthritis (a diagnosis correct in the radiologic sense but incorrect in a clinical sense) ¹⁷⁷

The comparative radiology of the two great types was noted by several ^{5, 172, 504, 535}. Taylor and his colleagues noted the following: marked systemic decalcification in 95 per cent of cases of atrophic, but only mild decalcification consistent with age in 75 per cent of cases of hypertrophic arthritis, also local decalcification in 13 per cent and 6 per cent, respectively, bone production (lippling and osteophytes) in 77 per cent and 100 per cent, "atrophic bone destruction" (punched-out areas) in 85 per cent and 9 per cent, "active bone destruction" in 11 per cent and 0 per cent, cartilage destruction (narrowing of joint space) in 95 per cent and 59 per cent, fusiform enlargement of soft tissue in 88 per cent and 9 per cent. Ankylosis occurred in 26 per cent of the atrophic, in only 6 per cent of the hypertrophic cases, in the latter only in the spine. Although individual features were shared by both types of arthritis, each possessed a basic pattern or grouping of features which makes roentgenograms very helpful in differentiation. The two types are radiographically distinct, even when they coexist in the same joint.

An appraisal of the diagnostic worth of the finer radiologic differences was made by Spackman who studied 1000 cases of chronic arthritis in patients aged 9 to 76 years: 474 with atrophic, 526 with hypertrophic arthritis.

Asymptomatic cases of the latter were not included. Changes in atrophic arthritis were as follows: in the early stage there were rarefaction of the trabeculated ends of bones, preservation of the zone of provisional calcification but irregularities therein, homogeneous haziness at joint space, at first widening, later narrowing of joint space. The earliest recognizable change was roughening or slight irregularity of the zone of provisional calcification, very minute projections of new bone into cartilage and small irregular areas of decreased density especially in the proximal border of the zone. In intermediate and late stages there was progressive ground glass atrophy, soft tissue swelling, disappearance of the line of provisional calcification and bony ankylosis of the joint. Changes in hypertrophic arthritis were as follows: in the early stage there were small, marginal osteophytes, narrowing of joint space, change in alignment of bones, thickening of the provisional zone of calcification, irregularity of the bony articulating surfaces, broadening of the circumference and secondary atrophy of the honey-comb type, in the intermediate and late stages, spur formation, Heberden's nodes, eburnation of bone, displacement and subluxation, punched-out areas, gross deformity and advanced secondary atrophy.

Morrison and Kuhns studied 55 cases of atrophic, 11 of hypertrophic and 7 of "mixed arthritis" to note the changes in serial roentgenograms taken from four to ten years or more apart. The changes varied greatly in different patients and in the same patient at different ages, and at different stages of the disease. The changes in atrophic and hypertrophic arthritis were not pathognomonic, and differed from those in the more acute and specific arthritides chiefly in the slow rate at which the former progressed. Marked changes were compatible with good function. Even though the radiologic changes were increasing, good functional recovery was possible. Changes in roentgenograms usually progressed long after the disease was clinically quiescent. Improvement in the roentgenologic picture was rarely seen, recalcification of bone and moderate repair were observed in the roentgenograms of only two patients. On a radiologic basis, Scott subdivided atrophic arthritis into "rheumatoid arthritis" and "infective arthritis," general decalcification being the keynote of rheumatoid arthritis, loss of cartilage with early bone sclerosis at the affected joints being the feature of infective arthritis. Others^{4, 535} found no radiologic basis for such a subdivision of atrophic (rheumatoid) arthritis. Aldred-Brown and Stevens did notice two "varieties," some with dominant local changes, others with dominant systemic bone changes. But they often occurred together and there was no evidence that the one type was associated with infection, the other, not.

Constitutional Differences, Anthropometric, Psychologic. Some affirm, others deny that atrophic arthritis occurs chiefly in the asthenic, and osteoarthritis in the pyknic, type. Anthropometric studies by Kovacs, Hartung and Hanscom on 50 patients with atrophic and 50 with hypertrophic arthritis revealed marked differences in constitutional morphology. Those with at-

rophic arthritis had a tendency to increased longitudinal measurements, longer and thinner necks, slender but not necessarily tall build, with weights normal or subnormal. Those with hypertrophic arthritis had a tendency to obesity, increased horizontal measurements, short thick necks, massive silhouettes.

(These 100 patients were all females, it would be interesting for the same investigators to make identical studies on males—Ed.)

Psychologic differences between patients with atrophic arthritis and those with hypertrophic arthritis were noted by Ellman and Mitchell, but not by Kovacs, Hartung and Hanscom.

ATROPHIC ARTHRITIS

Incidence Factors influencing the incidence of this disease are similar to those which influence rheumatic fever. Atrophic arthritis rarely appears among native whites or Indians in the Arizona desert.²⁶⁹ Winter produces its harmful effects by cold and damp, not by cold alone.⁶⁹ The patient's resistance is lowered by overheated houses and excess clothing, by the greater incidence of colds and tonsillitis which may provoke the disease and by a lack of adequate exercise and sweating. The peak incidence in the cases of Dawson and Tyson was between February and April. The disease is rare in children, only 10 of 800 patients seen by Dawson and Tyson were under 12 years of age. Among Pemberton's 300 patients of all ages 3 per cent were children. To Irons the influence of heredity seemed obvious; the disease often appeared in grandmother, mother and daughter. In Dawson and Tyson's series the familial incidence was 15 per cent.

Symptoms and Course Some English writers spoke of two varieties: 1 "Primary rheumatoid arthritis" or "rheumatoid arthritis" is of insidious afebrile onset and is accompanied by no marked inflammation and no obvious or related foci. 2 "Secondary rheumatoid arthritis," "chronic infective arthritis," or "focal arthritis" usually is of acute or subacute febrile onset and is accompanied by considerable inflammation and obvious foci to which it is supposedly secondary and after removal of which notable improvement is expected. Because the basis for complete separation of these two varieties is not clear, the American Rheumatism Association has not recognized such a subdivision of atrophic (rheumatoid) arthritis.

Complications Cardiovascular disease occurs only with the expected frequency in patients with atrophic (but with increased frequency in those with hypertrophic) arthritis, according to Monroe and Walcott. In 142 patients with atrophic arthritis cardiac enlargement occurred in 6 per cent, hypertension in 10 per cent, arteriosclerosis in 11 per cent, varicose veins in 5 per cent. Cardiovascular decompensation was rare, angina pectoris did not occur in this series.

Rheumatic iridocyclitis occurs not infrequently in children with chronic

polyarthritis, it often has a chronic course, causing ribbon-like keratitis. Holm reported a case in a 15 year old gull with Still's disease (adenopathy but no enlargement of liver or spleen). The probable rheumatic nature of primary juvenile iridocyclitis should be kept in mind. In such cases the iridocyclitis may come before, with, or after the arthritis.

Atrophic Arthritis and Splenomegaly, Still's Disease, "Felty's Syndrome" The association of arthritis with splenomegaly, sometimes with adenopathy, hepatomegaly, anemia and leukopenia or leukocytosis was described by Chauffard and Ramond (1896), Still (1897), Herringham (1909) and others, more recently by Felty (1924). The third review contained comments on the relationship between these syndromes, particularly on whether Felty's syndrome was different from or identical with Still's disease. Williams reported a case of Felty's syndrome with necropsy findings, he considered it not identical with Still's disease, but a blood dyscrasia in which there is an arrest in the maturation of polymorphonuclear leukocytes. Singer and Levy, who also reported two cases with necropsy findings, concluded that Felty's syndrome and Still's disease were slightly different varieties of the same disease, both being manifestations of sepsis lenta usually from green-producing streptococci. Features of the Still-Chauffard syndrome as described in European literature were summarized by Singer and Levy. Williams noted the characteristics of the nine cases of "Felty's syndrome" so far reported. The disease appeared in persons aged 45 to 65 years, of either sex. Features were weight loss (average 40 pounds), intermittent moderate fever (99° to 101° F), chronic polyarthritis with repeated acute migratory exacerbations, roentgenograms showing "infectious arthritis" or mild indeterminate changes, splenomegaly (all nine cases), hepatomegaly (two of nine cases), pigmentation of skin (six of nine cases), slight general lymphadenopathy (five cases), leukopenia (800 to 4200 cells, av 2500), 14 per cent to 79 per cent (av 50 per cent) polymorphonuclears, 1 to 12 per cent eosinophiles, 14 per cent to 86 per cent (av 40 per cent) lymphocytes, occasional myelocytes. (All of these features are often seen in cases of atrophic arthritis—Ed.) In William's own case cultures of blood in life and of liver and spleen at death were negative, the patient died of pneumonia, lung cultures revealed green-producing streptococci. Blood cultures in the cases of Singer and Levy revealed green-producing streptococci before death.

(Further observations will be necessary before one can form a final opinion on the relationship between Still's disease and Felty's syndrome. From data at hand we believe they are both varieties of atrophic arthritis. That Felty's syndrome is a sepsis lenta does not appear to be proved. Many chronic wasting illnesses terminate with a bacteremia of one sort or another—Ed.)

Relation of Atrophic Arthritis to Other Diseases Possible relationships between atrophic arthritis and rheumatic fever, and tuberculosis and atrophic arthritis, were discussed under "rheumatic fever" and "tuberculous rheumatism."

Pathology With Deacon, Ghormley again stated that the focal collections of lymphocytes in synovia and adjacent bone marrow are the distinctive pathologic features of the disease. Present early and late, they bear no relationship to the duration of the disease. Contrary to the opinion of Fisher (1929) and of Jordon, the collections are not perivascular, as can be seen when tissues are stained with the Perdreau stain. Miller³⁶⁸ regarded the focal collections as "evidence that rheumatoid arthritis is an inflammatory disease of probable bacterial origin."

Roentgenographic Features These were discussed

Laboratory Data, Blood Counts A left-shift in the Schilling hemogram was noted by Cecil in 68 per cent of 28 cases, by Collins in 97 per cent of 59 cases. Unaffected by removal of foci, it was found even in cases of long duration. "The persistence of the shift lends support to the view that this disease is truly infective in nature and that the infection is not a transient phenomenon during the inception of the disease, which is often pyrexial, but continues as an infection capable of exerting its influence on the nuclear count for many years." Hartung, Davis, Steinbrocker and Straub found the nonfilament count elevated above 16 per cent (av count 30 per cent), in 96 of 100 cases of atrophic arthritis. Of 100 cases of hypertrophic arthritis the count was elevated in 53 (av count 22 per cent), normal in 47. "The high incidence of an elevated nonfilament count in atrophic arthritis suggests the presence of an infectious agent." A normal count indicates that atrophic arthritis is very likely not present.

Sedimentation Rates and Blood Proteins Davis noted the following sedimentation rates: 43 to 125 mm (1 hour) in eight severe cases, 15 to 80 mm in eleven moderately severe cases, 28 to 62 mm in five clinically arrested cases. The rate demonstrates roughly whether there has been a change in globulin or fibrinogen or both, provided correction is made for cell volume. Theoretically a diminished rate is not always an accurate index of improvement from vaccines, certain of which cause a rise in globulin which per se may increase the rate. Such was not the case with Davis' use of hemolytic streptococcus vaccine. In atrophic arthritis there was a rise in globulin, especially euglobulin, and in fibrinogen, a fall in albumin. These findings suggested to Davis that atrophic arthritis is an infectious disease.

The plasma cholesterol tends to be low in atrophic arthritis (high in hypertrophic arthritis). Serum calcium was normal^{130, 243}

Gastric Analysis Deficient gastric acid was present in 60 per cent of Collins' female and in 17 per cent of his male patients. It bore no relationship to the degree of left shift in nuclear counts. Fletcher noted gastric subacidity in 50 per cent of patients studied, many were anacid to alcohol, a few even to histamine. He estimated that anacidity is five times as frequent among arthritic patients as among normals. Histamine-refractory achlorhydria was found by Moltke and Ohlsen in 36 per cent of 30 cases of

atrophic arthritis The high incidence of achlorhydria was not accounted for by age or sex incidence "It possibly predisposes to the disease and may be a factor of much significance Perhaps it is an expression of an infective process of gastric mucosa which is responsible for the poor nutrition of the arthritic"

(How can achlorhydria be of primary significance when it is so inconsistently present? Gastritis has not been noted at necropsy in atrophic arthritis—Ed)

Synovial Fluid The cytology of 52 synovial fluids from 31 patients was noted by Collins to be as follows total nucleated cells, 5060 to 56,000 (av 20,170) per cu mm, differential count (in per cent) polymorphonuclears 41 to 95 (av 80), lymphocytes 3 to 45 (av 16), monocytes 1 to 14 (av 3), macrophages 0 to 3 (av 0.3), synovial cells 0 to 3 (av 0.4) The total protein per cent was 2.7 to 8.5 The polymorphonuclear count depends on three factors depth of the inflammatory process within synovial tissues, extent of synovia involved, type of inflammation present—acute, subacute or chronic

ETIOLOGY AND PATHOGENESIS OF ATROPHIC ARTHRITIS

Factor of Infection 1 Foci of Infection On the basis of the literature under review the pendulum could hardly swing farther away from the subject of foci of infection and keep it alive While many writers commented academically on the subject, less than a half dozen reported new investigations thereon Cultures of foci made in the usual way reveal more germs than those made by the pathogen-selective method (Solis-Cohen, 1927) but most of the bacteria thus isolated are of no significance, according to Murphy In the pathogen-selective method the patient's whole fresh blood may inhibit the growth of nonpathogenic bacteria, thus allowing the "specific" organism to grow out in pure culture Among 107 patients with "chronic arthritis" Murphy's results, by the usual and the special method respectively, were as follows positive cultures from nose in 100 per cent and 47 per cent from throat in 100 per cent and 79 per cent, from feces in 100 per cent and 24 per cent, from urine in 61 per cent and 34 per cent Bacteria recovered by both methods were streptococci and staphylococci the former more often from throats and feces, the latter from nose and urine

(Because of insufficient data no significance can be attached to these figures Although the four cases reported seem to have been of atrophic arthritis, no evidence was given as to the type of "chronic arthritis" present in the other cases No animal injections were made to support the contention that the bacteria isolated by the pathogen-selective method were more significant Their significance was assumed on the basis of results from vaccines—Ed)

An infected prostate is an important, often a more dangerous, focus than others because it so often escapes detection, according to Duncan Of

752 males with "chronic arthritis" who had prostatic examinations 41 per cent had definite prostatitis, 40 per cent had a history of gonorrhea. Prostatic foci were commoner than oral foci as the latter had often been removed.

(No bacteriologic work was reported. A clinical relationship was assumed on the basis of improvement in joints during prostatic therapy—Ed.)

Foci of infection of "etiologic importance" were present in 72 per cent of the cases of Davidson and Goldie, oftener in tonsils, throat and sinuses than in teeth. Asymptomatic colon bacilluria, noted in 8 of 24 cases, was considered of etiologic significance by Slot and Deville. In spite of such data, Joseph Miller concluded that there was no convincing clinical or experimental evidence that chronic foci of infection are responsible for atrophic arthritis. According to Fisher, the National Committee on Chronic Rheumatic Diseases of the Royal College of Physicians were of the opinion that the etiologic import of toxic foci is often exaggerated, although in some cases foci appear to be important, on the whole their significance has not yet been definitely established.

2 Blood Cultures Positive blood cultures were obtained by McEwen, Alexander and Bunim in 19 (54 per cent) of 35 cases: hemolytic streptococci in three, green streptococci in nine, indifferent streptococci in five, diphtheroids in three cases. Cultures were positive (for green-producing streptococci) in 5 per cent of 44 normal controls, in 25 per cent of senescent nonfebrile states. Therefore the streptococci recovered from the arthritic patients were considered unrelated to the disease. Without discussing their significance, Cecil stated that the bacteria isolated by him and by others were actually in the blood and not contaminants. Cultures of blood and joints made by Davidson and Goldie were "consistently negative" (no figures given).

3 Cultures of Joints The studies of Hadjopoulos and Burbank led them to propose the following hypothesis: If the cause of atrophic arthritis were a specific, immutable microorganism with stable immunogenic properties, the disease should resemble other acute infections and end by recovery if the system uses its defensive forces effectively, or by death if it is overwhelmed by extremely virulent invaders. But if the disease were due to a streptococcus capable of dissociating into microbic forms more resistant to the immune mechanism, the natural tendency of the host would be to encourage such a metamorphosis. At operation cultures were made from joints in 20 cases of atrophic arthritis: they were sterile in two inactive cases of arthritis, revealed diphtheroids in two slightly active cases, *Staphylococcus albus* or *aureus* and diphtheroids in eleven moderately active cases, streptococci in three active cases (green-producing in two, hemolytic in one). One patient with subacute tenosynovitis yielded *Micrococcus tetragenus* and sarcina, one with acute bacteremic arthritis yielded *Streptococcus hemolyticus*. One culture of hemolytic streptococci during a period of three months passed

through all these stages. It was concluded therefore that atrophic arthritis is caused by a multiple mutant infection—at first by a streptococcus which gradually changes into a diphtheroid, staphylococcus, or “*Micrococcus sarcina*” This may explain why sera of arthritic patients frequently react to a variety of apparently unrelated organisms

(This interesting work needs considerable repetition for its final acceptance—Ed)

4 *Agglutinins* It was reported again that most patients with atrophic arthritis possess agglutinins to hemolytic streptococci, generally in high titer, a few also possess agglutinins to green-producing streptococci usually in rather low titer (table 1). Agglutinins were not strain specific and tended to diminish eventually disappear, as recovery took place. Of 36 patients with active atrophic arthritis McEwen and colleagues noted agglutinins to hemolytic streptococci in 85 per cent, in a dilution of 1:20 in 6 per cent, 1:40 in 3 per cent, 1:80 in 20 per cent, 1:160 in 8 per cent, 1:320 in 6 per cent, 1:640 in 42 per cent. No agglutinins were present in three cases of inactive atrophic arthritis or in 35 normal controls. Hartung and his colleagues noted agglutinins to hemolytic streptococci in “significant dilutions” (1:160 or over) in 24 to 36 per cent of cases depending on the strain used, in only 10 per cent of controls, agglutinins to various strains of green-producing streptococci in 4 to 16 per cent of cases. Fewer agglutinins were present to hemolytic streptococci from fatal septicemia than to those of less virulent nature. Davidson and Goldie noted hemolytic streptococcal agglutinins in a titer of 1:200 in 75 per cent of cases of atrophic arthritis, in 5 per cent of controls. Figures reported by Goldie and Griffiths were agglutinins to hemolytic streptococci (titer 1:100 or over) in 89 per cent of patients with atrophic arthritis, in 71 per cent of those with nonstreptococcal diseases, in 10 per cent of controls, agglutinins to green-producing streptococci were present in dilutions 1:100 in only 5 to 7 per cent of arthritic patients and controls. In sera of 76 patients Dawson and Olmstead found agglutinins practically only to streptococci Lancefield group A, not to groups B to G.

5 *Precipitins* Strong precipitin reactions to C substance of hemolytic streptococci were observed by Dawson and Olmstead only in those sera which gave strongly positive agglutination reactions, that is, precipitation reactions in atrophic arthritis were characteristic only for group A hemolytic streptococci. The presence of common antigenic constituents produced a small number of cross reactions with extracts of other groups. Results of Chasis and McEwen were similar except for a greater number of cross reactions, the non-group-specific fraction present in bacteria and in the crude C-extracts responsible for these cross-reactions is not the nucleoprotein or P fraction, it is apparently nonprotein in nature. McEwen, Alexander and Bunim noted strong and frequent precipitations to group A streptococci not only in patients with atrophic arthritis, but also in those with rheumatic fever, with

known hemolytic streptococcal diseases and even in 24 per cent of normal controls. The test is therefore of no value in differential diagnosis.

6 *Antistreptolysins* (*Antihemolysins*, *Anhemolysins*) Dawson and Olmstead noted increased antistreptolysins in "early" cases of atrophic arthritis (less than one year's duration), particularly in those of acute or subacute onset, but not in most "late" cases (over one year's duration). The average value in 40 early cases was 125 units (in 26 it was 125 or more), that in 151 late cases was only 51 units, that in 91 controls was 62 units, only five controls having 125 units or more. McEwen and colleagues found increased antistreptolysins (over 150 units or more) in only 9 per cent of their cases of atrophic arthritis (in 3 per cent of normal controls, in 80 per cent of rheumatic fever patients). Longcope also noted distinctly lower antistreptolysin titers in atrophic arthritis than in rheumatic fever, of 55 arthritic patients 46 per cent had over 100 units, only 18 per cent had titers above 200 units. About 25 per cent of the patients of Goldie and Griffiths had 200 units or more, about 50 per cent had 100 + units.

7 *Antifibrinolysins* Sera of patients with atrophic arthritis contain some, but not as much, antifibrinolysin as that of patients with rheumatic fever. Of 11 arthritic patients, 36 per cent possessed "definite resistance," 18 per cent possessed "marked resistance," to fibrinolysis³⁸⁹. Similar resistance was noted in many normal controls. Stuart-Harris found much lower values for antifibrinolysins, none in 54 of 60 patients, partial resistance (that is, some antifibrinolytic activity) in 4, "complete resistance" (that is, marked concentration of antifibrinolysins) in only 2. Conclusions were that hemolytic streptococci were related to rheumatic fever but not to atrophic arthritis.

8 *Streptococcal Skin Reactions* Positive skin reactions to hemolytic streptococci were obtained by Goldie and Griffiths in 76 per cent (with a concentrated solution) and in 28 per cent (with a weaker solution) of their cases of "chronic infective arthritis", in 24 per cent and 0 per cent of controls. Positive skin reactions to green-producing streptococci were noted much less often, with a strong solution in only 11 per cent with a weaker solution in about 9 per cent of arthritic patients and controls.

Interpretation of Immunologic Data The presence of these antibodies (table 1) in patients with atrophic arthritis is strong presumptive evidence that hemolytic streptococci may play some rôle in the production of the disease. But if hemolytic streptococci are etiologically related to both rheumatic fever and atrophic arthritis it is difficult to explain the immunologic differences between them⁸³. Some of the reactions are sufficiently distinct to be useful in differential diagnosis. Agglutination and precipitin tests tend to parallel one another as do antistreptolysin and antifibrinolysin concentrations. Agglutination and precipitin reactions are strongly positive in atrophic arthritis, weak or absent in rheumatic fever, but antistreptolysins and antifibrinolysins are usually markedly present in rheumatic fever, absent

or weakly present in atrophic arthritis. Although agglutinins and precipitins are increased in atrophic arthritis they may be nonspecific antibodies, comparable to the Wassermann and Weil-Felix reactions (Myers). Some believe that the hemolytic streptococcal infection is of a different nature in the two diseases, the same agent producing a different response in each.¹³⁵ At present, obvious deficiencies in these tests exist, already discrepancies have appeared in the results of various workers. Until these difficulties are corrected, no final interpretation is possible.

Bacterial Allergy Although bacteria play a rôle, no one specific germ causes chronic arthritis, according to Holman, it is not the germ or germs alone, it is "largely a question of the time, the place and the germ." In spite of inconclusive skin tests with bacterial proteins, Young favored the theory of bacterial allergy. Ghormley and Deacon believe the disease to be related to bacteria even though the cellular reaction in synovia is not as one would expect from intra-articular bacteria. Perhaps the focal lymphocyte collections in synovia represent an allergic response to some bacterial or other toxin. Miller believed it impossible to explain the pathologic process on an allergic basis. Myers regarded the theory inadequately supported and unproved.

Virus Theory Although this theory seemed attractive to some,²²⁸ no further data in support of it were reported.

Factor of Circulatory Disturbance No new data on circulatory disturbances as a cause of atrophic arthritis were presented. The primary importance of such a factor seemed unproved to Myers. Histologic examination of affected synovia reveals, not vasoconstriction but a large blood supply and many open capillaries. Atrophic arthritis is a rare complication of thromboangitis obliterans, arteriosclerotic occlusion, Raynaud's disease or scleroderma.

Factor of Altered Metabolism, Carbohydrate Forbes and his colleagues considered the effect of a high carbohydrate diet harmful. But when Bowen and Lockie gave high carbohydrate (425 to 500 gm.) high calorie (2200 to 2700) diets daily for 15 to 65 weeks to eight patients with advanced atrophic arthritis no exacerbations were produced. By this diet arthritis was made neither worse nor better, but weight gains and improvement in skin texture and general nutrition were noted. The sugar tolerance of 49 arthritic patients (23 with atrophic, 15 with hypertrophic, 11 with mixed, arthritis) was tested by Peers, using the old routine test which showed delayed removal of sugar in 83 per cent, and by the new Exter-Rose test which showed abnormal curves in 57 per cent of cases. Peers concluded that the older test was more accurate and that the abnormal sugar curves reflect a constitutional disturbance of secondary, not etiologic, import. According to Myers many studies on sugar tolerance curves have been "unconvincing," done without due regard to certain factors (patient's age, nutrition, amount of sugar actually absorbed, and so forth). Carbohydrate indigestion is not

limited to arthritic patients, and when present, usually follows rather than precedes arthritis

Calcium Wootton vaguely referred to atrophic and hypertrophic arthritis as "end results of serum-calcium vagaries" No supporting data were given

Sulfur Metabolism and Hepatic Dysfunction According to Forbes and his coworkers indoluria is usually present in "chronic arthritis" (and other conditions), generally parallels the activity of the disease and disappears when joints markedly improve Indole may arise from foci of infection, or, when these are absent, possibly from intestinal decomposition of tryptophane, indole being either formed in abnormal amounts or allowed to pass through the liver not detoxified Sulfur is necessary for its detoxification and conversion into indican (potassium indoxyl sulfate) Indoluria may indicate impairment of hepatic detoxification resulting from a sulfur deficiency in the liver Reputedly the sulfur content of articular cartilage and of fingernails is low in arthritis Forbes and his colleagues produced "typical arthritic changes" in joints of rabbits by the intra-articular injection of small amounts of indole

(Many substances will produce them—Ed)

Perhaps indole, passing undetoxified through the liver with other toxic substances which gain similar entrance, is a contributing factor in chronic arthritis On the basis of this hypothesis high sulfur-low carbohydrate diets were given 22 patients with atrophic arthritis and to eight with hypertrophic arthritis, most of whom had indoluria Twenty of the former and five of the latter "improved markedly" Coincident with improvement, indoluria ceased Some patients whose diets were interrupted noted return of joint pains Since the diet was low in carbohydrate and rich in sulfur and vitamin B it was admittedly impossible to ascribe relief to the sulfur alone

Vitamin Deficiency Deficiency in vitamin B, C or D has been regarded as an associated factor in the production of chronic arthritis of either type Fletcher has suspected a latent deficiency in vitamin B Recently Rinehart and his coworkers attempted to establish vitamin C deficiency as an etiologic factor in both atrophic arthritis and rheumatic fever The basis for this idea was noted previously²⁴⁷ and was restated According to Rinehart, vitamin C deficiency in guinea-pigs produced a painful deforming arthropathy resembling atrophic arthritis—synovial proliferation, pannus formation and periarticular fibrous thickening Superimposed infection sometimes accelerated and accentuated these pathologic processes which included changes in bone, muscle and skin Normal plasma values for ascorbic acid are 0.7 to 0.9 mg per cent, levels below 0.7 mg per cent are suboptimal, those below 0.5 mg per cent are low (Rinehart, Greenberg, Baker) Low values (0.14 to 0.66 mg per cent) were noted in 21 patients with atrophic arthritis on their usual diet High values (0.90 to 1.39 mg per cent) were noted in 12 arthritic patients given an intake rich in vitamin C (Six pa-

tients with hypertrophic arthritis had normal or high values—0.90 to 1.34 mg per cent) Although low levels of plasma ascorbic acid are not peculiar to atrophic arthritis and in a given case do not indicate the existence of scurvy, these consistently low values in arthritis seem significant. The mechanism involved is unexplained.

(In this connection, and apropos of Hench's observation (1933) that notable jaundice temporarily "inactivates" atrophic arthritis and fibrositis, the observation of Sendroy and Schulz is of interest: jaundice seems to increase urinary excretion of ascorbic acid. "In cases of icterus, the abnormal titration of the urine may be caused either by the increased excretion of reducing substances other than ascorbic acid, or by a real disturbance in the ascorbic acid excretion or utilization process"—Ed.)

Because several patients with atrophic or hypertrophic arthritis improved while on concentrated vitamin D, Livingston assumed that arthritis is associated in part with a vitamin D deficiency.

Food Allergy and Dietary Habits Young noted that patients with atrophic arthritis are apparently abnormally susceptible to skin allergy (urticaria and allergic dermatitis) but not to hay fever or asthma. Hay fever or asthma or both were present in 15 per cent of 200 arthritic patients, in 14 per cent of 50 controls. Skin allergy was present in 32 per cent of arthritic patients, in 12 per cent of controls. However, only 4 per cent of 50 patients with allergic dermatitis and 2 per cent of 50 patients with urticaria had arthritis. In spite of the susceptibility of arthritics to skin allergy, skin reactions to food or bacterial proteins in 20 patients were of little value. Even in cases in which a known food sensitization was present, articular symptoms were not aggravated by ingestion of foods to which patients were clinically sensitive. Fifteen arthritic patients with skin allergy from known foods were fed the irritating food repeatedly, at no time was the arthritis affected. Young's results therefore do not support the idea that arthritis is caused by dietary disturbance or food allergy.

(A case of allergic synovitis presumably due to English walnuts was reported by Lewin and Taub and will be noted later.—Ed.)

Intestinal Toxicosis "Though there is not sufficient laboratory or clinical evidence to show that [atrophic] arthritis is a definite disease due to errors in metabolism, clinically I believe that the primary form is metabolic and probably due to some imbalance in endocrines" (Pringle). Thus many writers vaguely blamed the disease on abnormal metabolic processes involving intestinal dysfunction, and endocrine imbalance. Others objected to the vagueness of the terms "imbalance," "dysfunction" and "metabolic error," and asked how they operate to produce arthritis. To them gastric anacidity, colonic abnormalities and carbohydrate indigestion, inconsistently present, are not the cause of arthritis but the result of prolonged illness²²². Current literature included no further data.

Endocrine Abnormalities With no support whatever one writer²²⁰ in-

criminated practically all the endocrine glands by name in atrophic or hypertrophic arthritis. In atrophic arthritis "usually the metabolic rate is below average and sometimes well below the limits of normal" (Fletcher). Statements such as this are not uncommon^{52, 531} and have been challenged by those who generally find normal rates. Peers noted metabolic rates below minus 9 in 14 of 39 cases of atrophic, in 17 of 28 cases of hypertrophic, and in 7 of 12 cases of "mixed" arthritis. But he concluded that "the true arthritic is a non-myxedematous individual". Low rates were not due to lack of thyroid hormone but were brought about in some other fashion and are merely another reflection of a constitutional disease.

(Certain of these low rates may be normal for the individual—Ed.)

Disturbance of the Sympathetic Nervous System No new data on this point were reported except the observation that sympathectomy provides relief to certain arthritic patients⁵⁹¹. But because sympathectomy does not completely arrest the disease consistently and because many arthritic patients do not have vasomotor disturbances even or until late in the disease, Myers concluded that the vasomotor phenomena, although they aggravate symptoms, are incidental and that a disturbance of the sympathetic nervous system is not the cause of arthritis.

(Obviously the cause of the disease is unknown. The editors of these reviews have been mildly criticized for not making a stronger case for the metabolic or endocrine theories, for "playing down" papers supporting these ideas. Regardless of our individual convictions we have tried to review all papers fairly, to "take them as they come". Indeed an admitted fault, perhaps a serious one, is that in our efforts to be impartial, repertorial rather than too judicial, and to give new or contentious ideas a hearing, we have been too inclusive, not exclusive enough, and have reported much inferior work herein. Paraphrasing the automobile advertisement when better and more papers on the metabolic and endocrine theories are available, the review will welcome them. Unfortunately in the absence of much concrete evidence in favor of these theories, papers thereon have been as a rule most speculative, hypothetical and philosophical. Although unproved, the infectious theory remains dominant by the content as well as by the volume of literature thereon. However, there seems to be a current reduction in the number of papers thereon and in the zeal of their authors. Investigations on foci and blood cultures have become momentarily less popular and interest has swung to the immunologic reactions involved. These are difficult to interpret. Indirect evidence is so much less satisfactory than direct evidence that some, confused by the uncertainty and contradictions thereof, are inclined to favor the infectious theory in spite of rather than because of, all the bacteriologic and immunologic data so far presented. The importance of beta hemolytic streptococci in the etiology of rheumatic fever and atrophic arthritis should be somewhat deflated if it is shown (as preliminary and unpublished reports seem to indicate it will be shown) that sulfanilamide, so effective in diseases of known hemolytic streptococcal origin, is of little or no value in rheumatism. If so one cannot escape the conclusion that such streptococci play a minor, not a primary rôle, or no rôle at all, in which case the antibody reactions thereto must be nonspecific—Ed.)

TREATMENT OF ATROPHIC ARTHRITIS

General Remarks Atrophic arthritis is a generalized disease requiring individualized treatment. A systemic disease, "it is no more a disease of joints than typhoid fever is a disease of Peyer's patches" (Pemberton). No single form of treatment is adequate. Lacking a specific remedy, physicians have too often, like the children of Israel, wandered afar after strange gods.²⁶⁹ Although some studies on therapy have been well controlled and have taken into consideration the natural history of arthritis and its tendency to spontaneous remissions, too many have consisted of uncritical observations of a few patients for a short time only and are of little or no value. The aggressive doubter will insist that the control method be used. "I could almost cry when I read of one case cured by drug X, knowing so well the vagaries of the disease even when untreated," so wrote one physician.⁴³⁸ In evaluating treatment one must rely most on objective improvement, less on the patient's subjective relief. Otherwise, one will be misled by the psychic effects inherent in any measure. "An enthusiastic physician may acquire at least a temporary reputation for great skill."³⁶⁸ Nevertheless, enthusiasm and optimism are essential, if the physician exhibits a lack of therapeutic resources his patient will catch the air of futility with resultant serious depression. In appraising the value of favorite remedies one must remember that "experts also are liable to fashions." One should not be mesmerized by a spa, a local focus, a diet, a drug, a vaccine, short-wave therapy or physiotherapy, neither should one be foolish enough to decry them.⁴³⁸ Among the pitfalls in a study of therapy is that of the dangerous but helpful drug: its full effects must be studied so carefully, for what seems to be a dangerous drug today (e.g. gold) may be improved by further knowledge. These were a few of the useful generalizations currently expressed.^{5J, 269, 279, 368, 438, 439}

Management of Foci of Infection Many regarded elimination of foci of infection the measure of first importance.²⁷⁹ Abhorring the promiscuous removal of foci one should nevertheless insist on the radical removal of any suspicious infection.⁴⁶⁹ One physician wrote sternly, "When an individual refuses to have definite foci removed, they are informed that both disease and cause are theirs to do with as they choose and are requested to seek advice elsewhere." Foci should be removed early in the disease, but Pemberton, Phillips, Holbrook and Hill considered it often necessary to raise the patient's resistance beforehand, this was done by a preoperative transfusion and periods of rest and weight-gain. Buckley sometimes noted "most remarkable improvement, even a cure" from removal of foci, occasionally a temporary exacerbation occurred.^{79, 531} Others were not so convinced of the value of removal of foci. Miller found the reports of favorable results therefrom unconvincing. Too often removal of foci was included with other therapy, thus clouding the issue, and the value of removal of foci is too often casually assayed on the basis of letters from patients. Miller considered it unfortunate that the removal of chronic foci is consid-

eried by so many to be the first and major treatment " This procedure has been responsible for the loss of much valuable time which might have been utilized more profitably in other directions " Fletcher suggested that some foci of infection may be merely an expression of poor health, not the cause of it, therefore arthritic patients may develop new foci during their disease The fact that the removal of foci of infection is not followed by rapid or notable relief does not, however, invalidate the importance of their eradication Several ^{59, 129, 569} insisted that results from removal of foci may be poor because often more than one focus is present, foci are too often imperfectly removed, indeed it is practically impossible to eradicate them completely as many " foci " are not local but diffuse (for example, nasopharyngitis), and joints themselves may be foci Lastly too much is expected of removal of foci in the presence of irreparable articular pathologic change

As in other things, there are fashions in foci and the literature mirrors these changing fashions Many who advocate eradication of foci will one year pounce on the prostate, another year on sinuses and so on One physician " had yet to see a case of arthritis from sinuses, gall-bladder, colon or prostate ", his own favorite focal enemy was situated elsewhere

Teeth No more than two infected teeth should be removed at a time (O'Brien) Only infected teeth should be removed, too often the wholesale removal of teeth to " clean up the mouth " causes serious nutritional difficulties for the edentulous patient

Tonsils These came in for very little notice

Sinuses Littell stressed the frequency of " silent sinusitis " especially in ethmoids Surgical treatment of sinusitis was applied in 20 cases of atrophic arthritis, 2 patients were unimproved, 3 slightly improved, 15 markedly improved

(Surgical operations on symptomless sinuses should be done only after much deliberation and when done their effects should be most cautiously appraised Only the most carefully controlled observations can determine whether or how often such a procedure is justified —Ed)

The importance and frequency of the *nasopharynx*,⁵² *cervix*¹⁶⁴ and *prostate*¹⁵⁵ as foci of infection were stressed One writer⁵⁴⁶ regarded the *gall-bladder* as a focus infected more often than suspected " Removal of bile through a duodenal tube may show that the gall-bladder is a carrier of streptococci, although the patient has no definite symptoms of cholecystitis "

(The isolation of streptococci from a duodenal tube after so-called duodenal drainage is not sufficient evidence to consider the gall-bladder infected Recent statistics^{245, 247} indicated the rarity of cholecystitis as a focus in atrophic arthritis and the rather unimpressive effects of cholecystectomy in this disease, even when markedly infected gall-bladders were removed —Ed)

Blake reported the case of a woman with epilepsy and atrophic arthritis of seven years' duration, spectacular recovery from both arthritis and epilepsy followed an appendectomy for acute *appendicitis*

(It is difficult to believe that the appendix was a focus here or that appendectomy had a specific effect. Similarly dramatic effects not infrequently result after any surgical operation from the effects of the anesthetic, the operation and hospital rest and regimen—Ed.)

Vaccines From the standpoint of literature this was not a very good year for the cause of vaccines. Wyatt, Hicks and Thompson administered to 240 patients with atrophic arthritis intravenous injections of an antigen from nonhemolytic streptococci. A marked or definite improvement was noted in 85 per cent, increased agglutinins in 80 per cent. Sedimentation rates were favorably affected. It was admitted that other forms of treatment were coincidentally applied and that no control series was set up. Davidson and Goldie gave very small doses of hemolytic streptococcal vaccine intravenously "with apparently successful results in some cases." No other data were given. "Fairly encouraging results" were noted by Lecklitner who used Crowe's *Micrococcus deformans* and polyvalent streptococcus vaccine in conjunction with other measures. Autogenous vaccines made especially from nasopharyngeal bacteria to which skin sensitivity was evident were used by Breuer. The "most amazing and apparently ridiculously small" doses were used. 100,000 or even 1000 bacteria might give no relief or even make the patient worse, but the use of 100 or even 50 bacteria "will produce remarkable results in a few hours." Using "specific autogenous vaccines" of streptococci or staphylococci or both cultured from various foci by the pathogen-selective method, Murphy noted relief in some cases even when staphylococci were used alone. Greer treated 50 cases of atrophic arthritis with "very small doses" of autogenous vaccine alone or autogenous and Crowe's vaccine given intravenously. A total of 88 per cent were improved. He considered the intravenous route superior to the subcutaneous one, since only 55 per cent of a former series of patients treated subcutaneously were benefited.

(The fact that in 15 of the 50 patients only one joint was affected makes one wonder how many of the cases were of atrophic arthritis—Ed.)

Some patients with persistent arthritis who were hypersensitive to streptococcal vaccine were found by Hitchcock to have staphylococcal sinusitis and to be hypersensitive to staphylococcal vaccine also. In 9 of 16 such patients the arthritis was benefited by the alternating use of staphylococcal toxoid and vaccine.

Comparing the results from different vaccines variously administered, against a control series, Holbrook and Hill were unable to prove vaccines of definite value. Nevertheless they continued to use them in some cases because of the clinical impression that certain cases were helped. With others they condemned the indiscriminate use of vaccine as a "specific remedy" to the neglect of other therapy. Doubtless many patients are somewhat benefited, but as Irons put it, vaccines are too often used as a sort of "occupational therapy" by the patient and the physician anxious for "some-

thing to do" Much of the previous work on vaccines was criticized by Kovacs because there were no controls, no routine assay of the activity of the disease was made or noted, sometimes the courses of vaccine were so long that spontaneous remissions could have occurred, usually additional therapy was given Reports on vaccines have been given by (1) those who noted excellent results in either atrophic or hypertrophic arthritis, (2) those who noted some results but only in atrophic arthritis and in conjunction with other therapy, and (3) those who noted no better results from vaccine than from other measures Kovacs gave various vaccines to 100 patients with "chronic arthritis" Although 30 to 40 per cent of each group noted some relief, controls treated by saline injections were similarly relieved

According to Buckley,⁵⁹ vaccines often do more harm than good Desensitization, not immunization, should be attempted, reactions should be avoided Best results were from progressively *smaller*, not larger, doses Others considered them "of doubtful value," "not routinely justified" ^{181, 431, 433, 546, 548} Holman expressed his opinion of them as a bacteriologist Nobody knows how they work, not even their most enthusiastic advocates It is impossible to evaluate them but there is little or no evidence that they are "specific" Using them, we are treading on uncertain ground "When we think we are immunizing, we may be desensitizing, and when immunity peters out we may then have an unexpected sensitization We are playing with a dangerous weapon in a confused field If I had arthritis, I might—but I doubt it—run the risk of interfering with the little understood balance of sensitivity and immunity by the use of vaccines or other suitable antigens if I were at all sure which were the responsible microorganisms in my case"

(It is difficult for a physician or layman without arthritis to say what he might or might not do were he to develop progressive atrophic arthritis Methods of treatment which seem quite unjustified, even risky, to the unaffected, frequently will be welcomed enthusiastically or endured philosophically by the sorry victims of this disease Although the patient's willingness to try anything does not release his physician from the necessity of adopting a critical and judicious attitude on any therapy proposed, the stubborn nature of the disease gives the harassed physician the right in individual cases to institute cautiously such therapy as vaccines, provided both the physician and the patient appreciate the difficulties involved and exercise care to avoid harmful reactions—Ed)

Foreign Protein Reviewing an experience of 20 years with triple typhoid vaccine injections, Miller noted that about 40 per cent of patients so treated had been entirely relieved from pain and tenderness after receiving three to five injections given once every other day Within a month, 50 per cent (of the 40 per cent) had a return of their disease Most of the remainder had a return of the disease after several months, perhaps a year A few had no recurrences in five to ten years The earlier in the disease they are given, the better the results

Venom Therapy Of patients treated by Mackenna with bee venom

("apicur") many were benefited, but since other treatments were given coincidentally it was impossible to say what caused the improvement. Beck noted "surprisingly successful results" in the treatment of an unstated number of patients with "arthritic and rheumatoid ailments" with bee venom, the hemorrhagic effect of which presumably produced an increased tissue oxidation. No physiologic or clinical data on cases treated were given. A 75 year old woman with chronic "hypertrophic" polyarthritis developed a severe allergic reaction from the sting of a wasp. Six weeks later she reported to Lincoln that her arthritis had been improved greatly since the wasp sting. She had not been so agile in years and was practically free from pain. The effect persisted for four months, then crippling returned.

Diets Although the arthritic patient still wants a special diet, the disease usually does not need one, that is the current opinion of most rheumatologists. Less is being written in favor of restrictive diets and special food combinations. As Swain said, until we know more about the disease we must be rational about diets for it. "The patient does best on that diet which would be selected for him if he had no arthritis" (Holbrook and Hill). If the patient is underweight these authors prescribe a high-calorie high-vitamin diet with no limitation of starches. Later, a high-vitamin weight-maintenance diet, low in starch, is given "not because starch is harmful but the starch eater will seldom eat enough food containing vitamins and minerals." The majority^{50, 279, 548} prescribed a high-calorie, high-vitamin diet except for the obese. A daily minimum of 50 to 75 gm of protein should be taken.¹⁸¹ Others^{222, 431} still curtail carbohydrates, but Bowen and Lockie noted no harmful effect from diets rich in carbohydrates (420 to 500 gm daily) given to 8 patients with atrophic arthritis for 15 to 65 weeks. Joints were neither worse nor better, but general nutrition was improved. On empiric grounds, Hare prescribed a raw vegetable diet to four patients with atrophic arthritis. Only raw foods were given for two weeks, then cooked foods were added. Two patients were not improved, two improved somewhat for five weeks. Sedimentation rates were unaltered. Relief obtained was ascribed to the diet's low sodium content producing marked fluid loss.

(No laboratory or clinical data to prove this were included—Ed.)

For reasons noted, Forbes and coworkers prescribed a high-sulfur low-carbohydrate diet. 20 of 22 patients were "markedly improved", two were not improved.

Additional Intestinal Therapy The general principles of gastrointestinal hygiene for arthritics were noted by Pemberton, Fletcher, and others. For those with achlorhydria, hydrochloric acid was prescribed.^{181, 546} Salol was used by some. Colonic irrigations were considered useful by some,¹⁰⁷ of no value by others.²⁶⁹ Adequate elimination is best promoted by proper

diet, abdominal exercises, massage, habit-time and not by cathartics. Breuer permitted small doses of magnesium sulphate before breakfast.

Vitamins Various vitamins were prescribed by those who regard vitamin deficiency as a contributing or predisposing factor. Vitamin A, generally as cod liver oil, was considered most useful, especially in winter.^{50, 181} Vitamin B, in brewer's yeast or wheat germ, was advocated by others.^{181, 269} Live yeast should be avoided, a few cases of toruliasis therefrom have been reported.⁵² Fletcher used generous amounts of orange juice and grapefruit juice to supply vitamin C, but no striking benefit accrued to a group of patients to whom Holbrook and Hill gave intravenous injections (150 mg) of crystalline vitamin C three times a week for several months.

After the method of Dreyer and Reed (1935) massive daily doses (150,000 to 250,000 U S P X units) of vitamin D (concentrated viosterol) were given by Vrtiak and Lang to 20 patients for 1 to 12 (av 3) months. Two patients showed marked, six moderate, four slight and eight no improvement. Results were not unlike those from other methods of treatment. Undernourished and anemic patients improved least. Roentgenograms in five cases before and after treatment gave no change in bone density. Signs of toxicity developed: nausea in all, frequency of urination and nocturia in a few. The series of cases was too small for an evaluation of vitamin D "but is sufficient to indicate [the need for a] conservative attitude" toward it. Vitamin D concentrate (Ertron) in daily doses of 200,000 to 600,000 U S P or International units was given by Livingston, alone to five patients, with fever therapy to nine other patients. Improvement was noted by four of the first, eight of the second group. Fever therapy plus vitamin D seemed to cause more rapid improvement than either alone. Toxicity was noted frequently, nausea, urinary frequency, lassitude, anorexia, polydipsia, diarrhea, severe gastrointestinal pain and vomiting. When toxic symptoms appear, administration of the drug should be discontinued at once for one to two weeks. Brewer's yeast was ineffective in preventing or ameliorating toxicity. In some cases improvement was not noted for from one to three months. Medication was continued indefinitely until maximal benefit was noted. Blood and urine calcium and phosphorus were unchanged. There was a right shift in Schilling hemograms, a decrease in sedimentation rates. Holbrook and Hill gave 200,000 to 350,000 units daily for four months to 25 patients. In five there was less pain, in four a marked drop in sedimentation rates. Irons expressed doubts as to the wisdom of giving vitamins in large doses to cure arthritis. "Neither is an immediate favorable effect on joints clearly proved, nor have the more remote and possibly unfavorable effects of massive doses of vitamin-concentrates on human tissues been determined."

Chronic hypercalcemia was produced by Fang and Miltner in albino rats by prolonged (six or more weeks) administration of large doses (2 to 5 mg daily) of irradiated ergosterol. Those on 2 mg daily showed weight gain

and no pathologic change. Those on larger doses developed marked skeletal decalcification with early cystic changes, metastatic calcification in heart and various blood vessels, and calcification of extra-articular collateral vessels of knee joints. Cartilage of knee joints and of intervertebral disks showed areas of degeneration and calcification—changes not unlike those of early human degenerative arthritis. There were no histologic changes produced in parathyroids to support the contention that vitamin D acts through them. Some of the rats which had developed hypervitaminosis were put back on a normal regimen, their tissues examined later. No histologic changes were visible, indicating that rats may recover completely from the effects of prolonged feeding of vitamin D within two to three weeks after the drug is withdrawn. Large doses of vitamin D produce a marked calorogenic action in normal dogs and rats. In thyroparathyroidectomized dogs, however, such doses produced no marked augmentation in metabolic rates, therefore Deutsch, Reed and Struck concluded that the thyrotropic effect does not concern parathyroids.

(Two of us, C H S and P S H, have given 250,000 to 600,000 U S P units of concentrated vitamin D to about 25 patients with atrophic arthritis, the drug being given daily (except for occasional short interruptions) for one to two years. Cures were not obtained, articular lesions were generally altered but little, but some of the patients noted reduction in pain and soreness and increased well being. Toxicity was frequently encountered and was inadequately controlled by brewer's yeast. Two instructed patients carelessly ignored signs of early toxicity and continued use of the drug one to three weeks longer. Their severe headache, anorexia, vomiting, weight loss, transient uremia and hypercalcemia promptly disappeared under appropriate treatment. When smaller doses were used toxicity did not appear—Ed.)

Transfusions Holbrook and Hill regarded transfusions as a valuable adjunct in treatment. In chronic cases no results were noted. In acute and subacute febrile cases, "good, sometimes dramatic results" were obtained, fever and swelling subsiding. The first two transfusions were given a week apart, later ones as necessary.

(It is particularly difficult to evaluate measures used in acute and subacute cases because more or less rapid diminution in inflammation is almost inevitable regardless of what is used besides rest and physiotherapy which the patient's joints generally demand—Ed.)

Medicines, Miscellaneous Substances Intragluteal injections of leukocyte concentrate were given by Hartung and Straub to ten patients for 3 to 40 weeks. None were cured, six noted symptomatic improvement. Blood counts and sedimentation rates were unaltered.

Insulin provides a "metabolic fillip" of value in debilitated cases with weight loss and anemia^{164, 222}. Ellman used 5 units daily the first week, an additional 5 daily units each week to a maximum of 30 units daily (15 units B I D). Insulin was given 20 minutes before the principal meal, which was followed in 3 hours by glucose or a glass of milk to avoid hypoglycemia.

The trend is away from drugs since most of them have not justified

themselves²⁷⁹ The fashion has now changed from arsenic and iodides to gold and sulfur, Fletcher doubted whether the change represented an advance Gutman listed scores of commercial preparations and their supposed indications Thyroid in small doses was prescribed for those with low metabolic rates as incidental, not as specific therapy^{52, 181, 548} Cinchophen was considered a useful, reasonably safe analgesic by some⁵⁰³ Rawls considered the use of amidopyrine safe in young arthritics, unsafe in patients with long standing atrophic arthritis or in elderly patients with hypertrophic arthritis Of 400 patients with different diseases who received variable amounts of the drug, four (1 per cent) developed agranulocytosis of whom three died Two had long standing atrophic arthritis, two had hypertrophic arthritis A study of the effect of prolonged doses of the drug on 100 arthritic patients (44 with atrophic, 66 with miscellaneous arthritides) was made, none developed agranulocytosis or apparent changes in leukocyte count Breuer regarded amidoxyl (ammonium-iodoxy-benzoate) "merely a fad which has just about passed out" Unfortunately, at least, six patients passed out with it, case reports of their deaths were collected by Hamilton whose results with it were "so poor that it has been long since discontinued" Macht and Mayo recommended bromsalizol (mono-brom-saligenin) as a superior analgesic Quick relief of pain results from the use of rhodan-calcium-diuretin, according to Zaki The Ru-Mari arthritis cure was exposed as an alkaline nostrum⁶²

Sulfur Having found colloidal sulfur and such sulfur-containing substances as contramine and iodolysin of no value Krestin gave "sulfosin" (1 per cent suspension of sulfur in oil) intramuscularly every five to six days Febrile reactions were induced in 40 patients with varying degrees of bony change "good results" (no symptoms, normal motion) were noted in 18, "considerable recovery" in nine, partial recovery in eight, no improvement in five Relapses within 4 to 24 months appeared in 25 per cent "Recurrence is not surprising, since there is no reason to believe that intramuscular sulphur affects the cause" It should not be given in the acute phase (exacerbations resulted), to elderly, feeble, or emaciated patients, to nervous, hysterical patients, to the very obese (they don't stand it well), or to those with tuberculosis or other "active organic disease"

(The cases were not well classified Some patients were hospitalized with bed rest No control group was studied Relief may have resulted from febrile reactions—Ed)

Ellman also recommended "sulfosin" reactions Breuer's results (not given) with colloidal sulfur given intravenously were "favorable in a small number of cases" Results of Holbrook and Hill with "sulfur injections" were "disappointing"

Gates considered sulfur "a forgotten remedy" worthy of reinvestigation "I have given sulfur in [arthritis, etc] when there was no indicanuria After giving it there was an abundance of indicanuria and the patient was

greatly relieved" The presumed virtues of a diet rich in sulfur were noted by Forbes and associates Miller concluded that no report to date contained suitable controls or careful objective studies of reputed improvement Periods of treatment were long enough for spontaneous remissions to appear

Gold Salts The treatment of arthritis by gold salts was instituted about 10 years ago British writers now speak of it as "very valuable" (Slot), "a therapeutic measure of the first order" (Baker), "the most important form of treatment for arthritis" (Hartfall and Garland) According to Tegner "It has always been regarded as unfortunate in Europe that the claims of chrysotherapy in the treatment of certain types of chronic arthritis have been virtually disregarded in America" If claims made for it are true, we probably deserve this chiding because until now no formal American report on the value of gold has appeared

The mode of action of gold in arthritis is unknown Intramuscular injections of gold are easier and as effective as intravenous injections²⁴⁰, oral administration seems ineffective¹⁴ Most workers now confine its use to atrophic arthritis Bach considered it useful in any "rheumatoid type of arthritis" with proliferative synovial reactions including gonorrheal and tuberculous arthritis It is said to be equally effective at any stage of atrophic arthritis but of limited value in spondylitis ankylopoietica^{14, 18} (In hypertrophic arthritis it is somewhat useful according to some,⁴⁹⁸ useless according to others^{14, 18, 59} It is said to be useless in rheumatic fever, muscular rheumatism and gout)

The drug is given in courses with free periods between, much as in the chemotherapy of syphilis Injections are given every few days, initial doses varying from 0.05 to 0.1 gm, the dose usually being gradually increased Differences of opinion exist on what constitutes one course it was variously limited to a total dose of 1 gm (Hartfall and Garland), 1.0 to 1.5 gm (Buckley), 1.2 gm (Slot), 1.5 gm (Phillips), 1.8 to 2.4 gm (Williams), 2 gm (Baker), 2.5 gm (Bach) Copeman's course for children totalled 0.25 to 0.50 gm Rest periods between courses varied four to eight weeks¹⁴, two to three months⁵⁹, three plus months²⁴⁰, six months¹⁸ The number of courses necessary for results varies, the majority believed that at least two courses were necessary and that many failures or relapses resulted because subsequent courses were not given Bach gave courses intermittently for 6 to 24 months

The management of such therapy includes frequent analyses of urine, blood counts and sedimentation rates to gauge progress and dosage and to avoid reactions if possible If after six to eight weeks of injections the sedimentation rate is not falling, a larger dose or a new preparation should be used, or one should stop the therapy¹⁴ Progress is slow, results may not be noted until after 8 to 12 injections Various gold salts were used allochrysine, sanocrysin, solganol B oleosum, myochrysine, myoral, crisalbine, lopion

Reactions were numerous, some incidental, others more serious, some fatal. Reactions at the site of injection were usually avoided by local massage. Focal reactions, joint pains for several hours, occurred in 5 per cent of Bach's cases. General reactions—fever, increased joint pains—occasionally occur, in which case the dose should not be increased. Toxic reactions were uncommon according to some, unfortunately common according to others, "considerably more common than most of us care to admit" (Crosby). They involve many tissues. Skin was commonly affected (in 5 to 10 per cent of cases¹¹), with erythema, exanthema, papular eruption, desquamation, soreness, morbilliform rashes, urticaria, and occasionally serious exfoliative dermatitis, cases of which were seen^{11, 123, 240, 275}. If skin reactions were local, courses were not interrupted, if general, treatment was interrupted¹⁴. Other tissues frequently affected were eyes (conjunctivitis), mouth (metallic taste, anesthesia of tongue, transient loss of taste, dysphagia, sore tongue and gums, ulcerative stomatitis), gastrointestinal tract (weight loss, nausea, vomiting, epigastric distress, diarrhea, rarely rectal spasm), liver (hepatitis, jaundice, rarely acute yellow atrophy),⁴⁹⁸ respiratory tract (cough, "gold bronchitis"), kidneys (generally mild, transient albuminuria, occasional uremia), central nervous system (one case of persistent eighth nerve deafness¹⁴), hematopoietic system (epistaxis, purpura hemorrhagica, aplastic anemia, agranulocytosis). While affections of other tissues may be serious, those of the hematopoietic system are most serious, occasionally fatal. Serious agranulocytosis and fatal purpura hemorrhagica were noted by Bach, fatal aplastic anemia by Hartfall and Garland. Additional toxic symptoms were headache, dizziness, tinnitus, sleepiness, fever, general malaise⁴³². When administered intravenously (which is not necessary) shock and pulmonary edema have been noted⁴⁹⁸.

Careful investigations of these toxic manifestations were made, notably by Hartfall and Garland, and by Crosby, reactions being analyzed in relation to many factors, individual and total dose, type of salt used, age and condition of patients and so forth. Williams and Bach believed that much toxicity could be avoided by the coincident injections of calcium gluconate but Crosby doubted its efficiency, and Hartfall and Garland noted no significant reduction of toxic manifestations. Others believed risks could be lessened by use of liver extract or glucose. Patients were warned to complain of any unusual sign or symptom. If eosinophilia of 7 to 8 per cent or more was noted, smaller doses were given¹⁹⁸. Contraindications to such therapy were arthritis with acute or chronic nephritis (since 75 to 80 per cent of the gold is excreted by kidneys, the rest by stools), diabetes, congestive heart failure, blood dyscrasias, hepatic insufficiency, possible contraindications were marked debility and hypertension. According to some, hypertension, age and arteriosclerosis are no contraindication^{18, 240}.

(Original papers should be consulted regarding prevention, amelioration and treatment of these complications and the plan of dosage for the various salts—Ed)

Results of treatment follow Hartfall and Garland who previously reported results in 100 cases, have reported results in 300 83 per cent were "apparently cured" (complete freedom from pain and disability other than that due to bony ankylosis), 69 per cent were markedly improved (some dramatically relieved), 15 per cent slightly improved, 5.6 per cent not improved, 0.3 per cent (one case) made worse, and 1.3 per cent died (four cases) [These deaths include the three noted in their first series, and one additional death from aplastic anemia] Various preparations were used crisalbine, solganol B oleosum, lopion, myocrysin They saw "results which were little short of miraculous in patients showing the severest grades of disability, and a number of those previously bed-ridden became ambulatory, while others discarded their crutches and sticks" Also noted were improved general health and appetite, weight gains, reduction in sedimentation rate Statistics indicated more cures, also more toxic reactions from crisalbine, to avoid which smaller doses than formerly should be used present initial dose 0.05 to 0.1 gm, maximal single dose 0.1 gm, maximal dose for 1 course 1.0 gm

Allochrysine was used by Baker "with uniformly good results" in an unstated number of cases Copeman reported two cases of Still's disease "cured" by allochrysine, which was also given by Crosby to 27 patients with chronic (generally atrophic) arthritis with these results nine greatly improved, eleven improved, three slightly improved, four not improved Crosby concluded (1) that gold therapy is "quite the most potent now available" but (2) it is "attended by not a little risk" and "should only be undertaken when the case is severe enough to warrant such a very real risk which should be explained to the patient before treatment is instituted"

Solganol B oleosum was used by Bach and Slot Bach stated that in early cases "a complete 'cure' may follow with full restoration of function" Half of his (unstated number of) cases "responded well" and the disease became "arrested" after treatment for from three months to two years Of Slot's twelve patients nine improved "satisfactorily," two failed to respond and one patient ceased treatment after a reaction Ellman treated 24 patients with "infective arthritis" with gold (solganol B oleosum) and 14 control subjects with almond oil Both groups noted a beneficial effect but especially those on gold Three of the latter, but none of the controls, were cured The sedimentation rate sometimes rose the first month, then began to sink to normal and remained there, whereas in controls it was variable, dropping only temporarily Tidy noted "undoubted improvement in several cases" but results were difficult to evaluate F. G. Thomson considered it "of doubtful value" (No data were presented)

American rheumatologists have certainly been "off the gold standard", until recently the only comment was that of Cecil (1934) who briefly dismissed his results as "not striking" Holbrook and Hill simply said that their results in an unstated number of cases were "disappointing" Brief reports by Oren and Phillips have appeared Of 66 patients treated by Oren with a water soluble gold salt 60 "responded very well" Results were en-

couraging because of the rapid response to treatment, the slight pain connected with the therapy and the lack of systemic reactions. Five or less courses were given. Phillips treated nine patients with myochrysine, only two were subjectively improved. Because of frequent toxic reactions, initial doses were reduced to 0.01 gm. He concluded that even with small doses the untoward reactions "constitute a hazard which should make us extremely cautious. Personally I do not, for the present at least, feel competent to handle this drug to the advantage of the patient."

(Phillips treated 20 patients: nine with atrophic, eight with hypertrophic arthritis, two with peripheral neuritis, one with subdeltoid bursitis. Of the group only six received a total of 1.50 gm., the amount which many regard as the effective minimum. Tegner, criticizing this report, stated that Phillips' selection of cases was poor — "more than half of his series could, in France and in this country [Great Britain] be regarded as unsuitable for chrysotherapy. One can hardly feel that chrysotherapy has had a fair trial in the United States." Miller's main objection to past reports was the lack of controls in practically all of them. This objection seems valid. Apparently definite benefit results from such therapy in an impressive number of cases, but until more controls are set up we will not know the exact value of the method and how fully justified one is to run the risk of the frequent and rather serious toxic reactions.—Ed.)

Vasodilators Histamine, Choline Subcutaneous injections of histamine acid phosphate were given at first daily, later two to three times weekly for four weeks by Eastwood to 70 patients (27 with atrophic arthritis, eight with osteo-arthritis, five with fibrositis, three with spondylitis, two with gout, 25 "indeterminate and mixed"). Results were analyzed for the whole group: 74 per cent improved, 26 per cent did not. Patients with early atrophic arthritis complicated by vasomotor changes did best. Worst results were in those with no circulatory disturbance. Results were analgesic and psychologic, not curative. Transient relief from pain, stiffness and vasomotor changes were noted. "Although transitory, an immediate response of this type is of value inasmuch as it shows a patient that his condition is not hopeless, that his pain can be removed, that freedom of movement can be restored, so an optimistic state of mind is produced." Shanson noted similar results: "sometimes dramatic and lasting, often transient and disappointing." Side-actions were noted: flushing, headache, sense of warmth, drowsiness, slight fall in blood pressure. Mackenna preferred histamine ionization. Although other types of rheumatism were affected, patients with atrophic arthritis were not relieved, some were made more uncomfortable. The method was discarded for that disease. Mecholyl (acetyl-B-methylcholine chloride, formerly called mecholin) iontophoresis was applied by Mathae to 32 patients with atrophic arthritis, 72 per cent had "good results." It is not a cure but an adjunct. Phillips gave 103 treatments with mecholyl iontophoresis to 20 patients with atrophic arthritis, only two were "improved." It was abandoned as useless. Mecholyl in doses of 50 to 1500 mg. taken orally is an effective peripheral vasodilator, after

its use Goldsmith noted an average maximal rise of 5.8°C in skin temperature of digits. An adequate dose (1000 to 1500 mg) could be repeated every few hours to maintain vasodilation. Histamine was considered useful in early atrophic arthritis by Buckley, of unproved value by Tidy.

Rest and Movement Wide approval of the principles of physiologic and mechanical rest was expressed^{179, 239}. Rest was called "the keynote of therapy,"⁵⁹ "the inevitable price of recovery,"⁵². Many extra hours of bed rest are necessary for the fatigued body as well as the joints of the arthritic.^{223, 431, 529} Inflamed joints should be put at rest in light plaster casts or splints.^{59, 60} Fisher preferred light metal adjustable splints to plaster of paris which has certain disadvantages, it imposes a further handicap on an already poor circulation of the rested part, excludes light and air, prevents easy application of physical therapy and impedes such active, painless motion as the patient may attempt. Kindersley and Burt favored complete immobilization of an inflamed joint for one week in a plaster cast, which is then bivalved and used as a splint. Many will agree with Buckley⁵⁷ "The idea that arthritics should be kept on the move lest their joints 'set' is responsible for much unnecessary suffering and has caused more crippling than it has prevented." Although a prescription for rest is vital when joints are markedly inflamed, as inflammation subsides rest for joints must not be complete lest permanent fixations occur.¹⁸¹ Active and passive painless motion must be encouraged and increased as possible.⁴⁸⁰ Swain described the postural and bed exercises which form the optimal combination with rest. Ghormley reminded us that synovial pannus grows over parts of the joint which are not in contact, if motion can be preserved, prevention of the growth of this pannus may be partially accomplished.

Physical Therapy In the treatment of the various rheumatic diseases, especially atrophic arthritis, physical therapy is widely recognized as "of supreme importance."¹⁶⁴ Thousands of crippled arthritics spend hundreds of thousands of dollars hunting vainly for the "elusive focus" or the medicinal "cure" but spend little or no effort or money on worth-while physical therapy. Other thousands contribute an annual income of \$105,000,000 to the quacks and irregulars licensed by the states to practice the physical methods too many physicians ignore (Hibben). Kling complained that physicians are now apt to over-emphasize the systemic phase of the disease to the extent that they forget to treat the joints as well as the patient, and sometimes even forget to examine the joints. On the tenth anniversary of its origin the Council on Physical Therapy of the American Medical Association noted the present status of physical therapy in this country, outlining principles which should be understood by all physicians concerned with the arthritides. This and other current reports review the therapeutic rationale and physiologic effects of various types of physical therapy for rheumatism.^{117, 173, 322, 324, 448} In Fletcher's opinion physical therapy "deserves the reputation it gained in Europe, not the neglect it has won on this side of the Atlantic."

There is a growing appreciation of the importance of teaching arthritic patients home physiotherapy. Seventy-five per cent of arthritic patients questioned by Hensch²⁴⁸ had previously consulted osteopaths or chiropractors, because their physicians had given them no physiotherapy, or given it haphazardly, "not enough to relieve," or because physical therapy in the physician's or professional physical therapist's office was too expensive, more costly than they could get it elsewhere. The "physical therapy high-brow" may scorn simple home procedures and consider it beneath his dignity to teach his patients the simple adjuvants which would sustain the effects of professional methods. But they are a lot better than nothing and fill the need felt by the patient who has sought relief from a hot bath, a strip of flannel and a hot iron, a farm oven or a bag of heated sand, salt or oats. If his physician does not tell him of better methods he will continue his amateur efforts or get cheap help from cultists. Noting the short sighted attitude of those who insist on "all-professional physical therapy or none" Coulter outlined the simple principles and methods available for the patient's home as well as the physician's office. Others also considered of the greatest importance the formulation and use of suitable methods for inexpensive physical therapy: simple apparatus for heating, methods for passive, assistive and corrective exercises, and for massage^{269, 279, 280, 548}

Many recognized the advantages of *hydrotherapy* and *balneotherapy* but disagreed sharply with the point of view of those spa physicians who seek to create an attitude of superior virtue for the water of a particular spa and who, perhaps to make the patient feel dependent on the spa, make no effort to teach the departing patient home physiotherapy in order to project into the patient's home environment at least some of the benefits of the spa. Miller conceded that spas provide superior opportunities for rest and relaxation and have a psychologic effect "but the water has no more value than that in the home bath tub." In Tidy's opinion "few of the so-called researches from spas have fulfilled the canons of scientific evidence and research." Many spas with widely different waters and climates produce the same results. Unless something more definite, or something common to many spas can be produced with scientific support, the profession and the public may decide the various claims cancel out and that the maximal benefit from therapy can be obtained without visiting a spa. There being no evidence that any ingredients of the water, peat or mud are appreciably absorbed by the skin, results must come from other factors—heat, rest and so forth. Some consider the ordinary hot bath at 100° to 120° F. for 20 to 40 minutes the most useful form of heat⁵⁶⁰. "Electric pads and hot water bottles are a joke, they produce no real benefit." Ellis favored the *Wilde hot bath*. *Ultra-violet* rays as the sole therapy are ineffectual, according to Pringle who favored hot *paraffin wax baths*. *Faradic currents* help to control muscle wasting⁵⁴⁸.

Conventional Diathermy, Short-Wave Diathermy Ordinary or "long

wave" diathermy utilizes wave lengths from 100 to 400 meters (theoretically from 30 to 500 meters, but no machines currently use wave lengths below 70, few below 100 meters) "Short-wave diathermy" (the Council-approved term synonymous with "short-wave therapy" "short-wave high frequency," "radiotherapy," "radiathermy"), concerns wave lengths from 12 to 30 meters "Ultra short-wave diathermy" (synonymous with "ultra short-wave therapy," and so on) utilizes waves of 3 to 12 meters in length In current dispute are arguments that short-wave and ultra short-wave diathermy are therapeutically superior to ordinary (long-wave) diathermy, that the different wave lengths in the short and ultra short range have different physiologic actions, and that short and ultra short-waves produce effects by a specific effect apart from their heating potentialities Those interested in general and technical details are referred to several papers^{111, 112-114 425, 502} Although some still believe otherwise^{29, 283, 284 315 460} the majority believe results are due solely to the heating effect of short or ultra short-waves, different lengths of which produce identical, not specific, effects^{113, 114 264 337 382} Kovacs concluded that the primary physiologic and therapeutic effects of long and short-wave diathermy are essentially the same, that burns are commonly produced by short-wave diathermy, that short-wave diathermy is technically more convenient but less efficient than conventional diathermy

Ordinary diathermy is useful in arthritis,¹⁵⁰ as useful as short-wave diathermy⁵³⁷ but over-rated⁵⁴⁸ and often disappointing in its effects^{111 112} Beneficial effects from short-wave^{506 582} and ultra short-wave diathermy^{311, 407} were noted in a few cases of atrophic arthritis

(The editors of the reviews believe clinicians in general will share their disappointment at the inadequacies of most "clinical reports" published in certain special journals on physical therapy These reports on arthritis rarely contain data on any controls, they make little or no attempt to differentiate the various types of arthritis being treated, if they do, they contain practically no clinical or laboratory data indicating the extent or severity of the disease from which one can base an independent opinion on the value of therapy As a rule a few representative "successes" are reported in the most cursory detail In technical matters they are often excellent, as clinical investigations they are generally very inadequate and disappointing The variations and vagaries of the arthritides being what they are, it is suggested that specialists in physical therapy team up with clinicians and "rheumatism specialists" to instigate those clinical investigations in physical therapy which are so long overdue—Ed)

Occupational Therapy The importance of occupational therapy as adjuvant to older forms of physical therapy for chronic arthritis needs continued emphasis²⁷⁸ In the management of almost every arthritic patient there is a time or a place when occupational therapy will accomplish results peculiar to itself and more efficiently than conventional physical therapy As Krusen, Macey and Pattee pointed out, these are not mutually exclusive or antagonistic forms of therapy, they should be correlated and interdependent, yet independent Featuring active exercises of a specialized and often highly individualized nature, occupational therapy is a most useful

addition to the more passive types of physical therapy. In the correction of arthritic deformities Cunningham and Shimberg found it very effective.

Roentgen-Ray Therapy Beneficial results from "wide-field roentgen-ray therapy" were noted by Scott in "spondylitis adolescens," but not in atrophic arthritis. Certain cases demand local radiation, others require general radiation. Deep therapy, the use of the more penetrating rays, is needed only for the hip joint, for other joint tissues more superficially situated the less penetrating rays are better. Scott stressed the importance of placing the joint under treatment in the optimal position for exposure of the full joint surface to the rays.

(No statistical results were given—Ed.)

Tidy considered deep roentgen-ray therapy for arthritis of unproved value.

Fever Therapy Effects of fever therapy in atrophic arthritis have been disappointing. Results are better in acute than in chronic atrophic arthritis. Thus, in Hench's survey of reported cases results were as follows: of 21 patients with acute atrophic arthritis, only 10 per cent became symptom free, 40 per cent were relieved. Of 147 chronic cases 10 per cent became symptom free, 25 per cent were benefited. Of 60 additional patients treated by Hench none were cured, only 20 per cent were definitely benefited. Of patients more recently treated, more than 50 per cent received little or no relief. Bierman noted temporary improvement in most cases, permanent results so rarely that fever therapy was not recommended. In the treatment of 40 patients, Stecher noted no cures, in about 30 per cent "substantial results" which were maintained 6 to 12 months. Thus, of 38 cases of chronic, and 10 of acute atrophic arthritis results were "very good" in 16 per cent and 30 per cent, good in 29 per cent and 40 per cent respectively. A fever session in acute cases was five hours at 105° F, in chronic cases three to four hours at 103° to 104° F. Short sessions of low fevers (½ to 1 hour at 101° to 101.5° F) were advocated by Atsatt and Atsatt as "metabolic boosts." (No results were cited.) McClure noted "satisfactory relief" in 46 per cent of 13 chronic cases. Of Neymann's ⁴⁰⁵ patients (not numbered) 15 to 30 per cent were greatly benefited, 30 per cent moderately relieved. Fifty patients were treated by Holbrook and Hill with "disappointing results." None were symptom free, 25 per cent were temporarily relieved.

Climate and Clothing The influence of these factors was discussed briefly by Burt and by Holbrook and Hill. Natives of the Arizona desert rarely develop atrophic arthritis and arthritic visitors have few exacerbations. However, climatotherapy is not a panacea for the disease, all other orthodox measures should be used.

Sympathectomy Bilateral lumbar sympathectomy was performed by McDonald in two cases of long standing Still's disease with marked swelling and deformity of many joints, muscle atrophy and cold, clammy extremities.

Thereafter the patients were more comfortable because of warm, dry legs and feet but "no obvious change was noted in the appearance or in the degree of movement of the affected joints" White recommended the operation only in cases of atrophic arthritis "when it is desirable to improve circulation per se in cold moist extremities" He had noted no relief of pain or increased mobility in five cases so treated A patient of Bothe, affected for six years, bedridden for several months, noted gradual but definite improvement which was notable the first two months after operation and continued thereafter Blocking the appropriate sympathetic nerves by alcohol injections was used by Patterson and Stansby as a substitute for surgical sympathectomy In 11 arthritic patients so treated, satisfactory increases in skin temperature were noted which persisted for an average of six months, average increases being 11.6° F at toes, 10.9° at fingers, 3.3° at knees, 5.6° at elbows Although symptoms of faulty circulation were definitely improved, the results for the joints were "very disappointing" two patients showed definite diminution of the arthritic process, the others showed little or no improvement

In sharp contrast to the above were the results of Young, who performed the operation on seven severely crippled patients with atrophic arthritis with "remarkable improvement" in each Most of them were bedridden, some with "extremely disabling polyarthritis" flexion deformities and "profound disablement of limbs" Noted very shortly after sympathectomy were "rapid relaxation of flexor spasms," banishment of pain, restored power of walking, "practically complete restoration of useful function," "rapid improvement in function of limbs, even of the most disorganized and disabled joints" (the latter comment referring to a case of eight years' duration with "marked deformities—almost complete disablement")

(In view of the past experiences and current reports of others it is very difficult to share Young's enthusiasm Although a brief sentence on the subsequent maintenance of improvement was given in two cases, concerning others in which operation had been performed two to four years ago no subsequent observations were noted Several of the patients noted marked postoperative improvement in upper extremities, nerves to which were not interrupted It was not stated how long this improvement lasted One of us (P S H) has followed all results of sympathectomy for arthritis with particular care as he was associated with Rowntree and Adson from the initiation of this work (1928), indeed helped choose the first and subsequent patients treated by them As a physiologic procedure sympathectomy for atrophic arthritis seemed rational but to those who originated and followed it from its onset it has given clinical results in the main disappointing Adson's current comment follows—Ed)

According to Adson "cervicothoracic and lumbar sympathectomy have been of value only in relieving symptoms and checking the disease in a small group presenting definite disturbances of sympathetic origin, characterized by vasoconstriction and hyperhidrosis The operative treatment does not alter deformities, contractures or the condition of ankylosed joints It

is of no value in the treatment of arthritic processes in larger joints—knees, elbows, hips and shoulders "

Bone Puncture (Forage) Further favorable results from bone puncture were reported by Mackenzie His reason for adopting this procedure (1931) was given previously²⁴⁵ an elderly arthritic patient, long crippled, broke a femoral neck, during convalescence her arthritis became, and remained, painless Mackenzie's procedure was an empiric approximation of this phenomenon He concluded that atrophic and hypertrophic arthritis ("essentially the same in origin") are the results of primary osteitis, arthritis being secondary thereto Treatment consisted of drilling "sufficiently large" holes in para-articular bone—in the lower end of the femur and upper end of the tibia when knees were involved, in the femoral neck, trochanter and acetabular margins when hips were affected Some marrow is scooped out "the whole idea being to bring about a state of decompression" In a typical case of "osteoarthritis" clear, oily fluid, "definitely under pressure," wells up, in it are white granules often larger than the head of a pin Cultures and microscopic examination of this material revealed "nothing of interest" After operation convalescence was generally uneventful The operation was done for hips or knees of 106 patients, statistical results were not given but "an improvement really worth while can be expected in 80 per cent of cases" The cause of relief was not known

(This procedure is not new in 1890 Noble Smith reported good results from "bone drilling in the neighborhood of inflamed joints and elsewhere" Similar results have been reported recently from France by Graber-Duvernay, 1932, 1933, 1935 definite improvement in seven of ten cases Simpson and Henderson noted "lasting relief from pain" in three of twelve cases of "hypertrophic osteo-arthritis" of hips, lesser improvement in four others—Ed)

Prevention and Correction of Deformities The well-known procedures for the correction or prevention of deformities were again reviewed^{59, 239 200, 288, 306, 368, 384, 480, 529, 530} They included the use of plaster splints and braces, and various operative procedures Discussed were the best type and safe duration of immobilization³⁰⁶ the use of oxygen insufflation to prevent or correct adhesions,^{257, 209} optimal positions for ankylosing joints, also for those where retention of function is anticipated^{239, 480} Points which cannot be too often emphasized were that with the cooperation of the physician and orthopedist deformities generally can be prevented by early treatment, or can be largely corrected once they have occurred, and that functional use of deformed joints can be restored by suitable orthopedic surgical and non-surgical procedures^{179, 250, 529, 530} Too often so-called cooperation between physician and orthopedist is merely a matter of lip-service, to be successful it should be vital, continued from the onset of the disease (Fisher) The various causes and types of adhesions were ably discussed by Jones adhesions may result from too little or too much motion of joints, from uncorrected edema, from joint manipulation or over strenuous physiotherapy

Besides the placing of pillows under knees, the "shortest route to the wheel-chair" is accomplished by the patient with painful bent knees who keeps walking no matter how much it hurts (Holbrook and Hill). When cartilaginous destruction has occurred, manipulation (active, passive or surgical) must be done with caution. Henderson stated, "If a joint is more or less fixed at a certain angle and use only changes that angle to another fixed angle, one must not manipulate it. When the range of motion is increasing one should trust to active motion, when it is not increasing, then only should passive movements be carried out, but not forcible manipulation." Manipulation under anesthesia requires more experience than any other procedure, one of the last things a young orthopedist should be encouraged to do. In an instructive paper Lewin listed 18 do's and don'ts in manipulation of arthritic joints. For the correction of flexed knees some believed posterior capsulotomy often necessary in addition to the use of manipulation and bivalved splints.^{57 269} Of 19 cases in which such treatment was given results were successful in 14 (Holbrook and Hill).

Psychotherapy Little attention has been paid to this factor, which is such an important and (from the standpoint of evaluating clinical results) so often an unrecognized feature of any treatment scheme. It is imperative that the patient be taken into his physician's full confidence and vice versa, that the patient be instructed fully in the problems that lie ahead, that he know the limitations and possibilities of his own and his physician's therapy, that the reason for good results but particularly for the bad results (which patients see about them and inevitably remember) be frankly discussed (Fletcher, Ellman). Social, emotional and economic adjustments are often required that the patient may be properly conditioned for the prolonged treatment so often necessary for success. Both physician and patient must realize there is no easy way to a "cure." Physicians should stop treating patients half-heartedly with each new remedy of doubtful value and concentrate on the few simple measures of proved worth.²⁶⁹

Prognosis, End Results According to Pemberton, 75 per cent of arthritic patients should experience great betterment or complete arrest, 20 per cent are more refractory perhaps because of a dominant continued infection, in 5 per cent therapy is of no avail. In Sweden a plan of hospital treatment and subsequent occupational adjustment has been set up. According to Kahlmeter, 70 to 80 per cent of patients leave the hospital fit for work. Enduring results were relatively frequent. 62 per cent of 1000 patients were earning all or part of their living three or more years after hospitalization. Other figures noted by Kahlmeter were those of Zimmer (57 per cent "definitely improved"), of a Silesian Insurance Institute (80 per cent relieved), of Danischewsky (52 per cent working) of Freund (36 per cent cured, 45 per cent improved). Of 452 generally "completely helpless" patients with atrophic arthritis discharged from the Robert Brigham Hospital, Boston, about 66 per cent of those living in 1935 were working,

21 per cent had had relapses (Kuhns and Joplin) The commonest diseases complicating convalescent care were arteriosclerosis in 41 cases, nephritis in 22, hypertension in 19, obesity in 17, myocarditis in 16, gonorrhea in 12, rheumatic heart disease in 10 There were 76 deaths, 18 from pneumonia, 13 from myocarditis, 11 from nephritis, 6 "postoperative," and 28 miscellaneous

HYPERTROPHIC ARTHRITIS

Definition In the following discussion "hypertrophic arthritis" means a clinical syndrome, not just a roentgenographic alteration, it is synonymous with senescent degenerative osteo-arthritis, or "primary osteo-arthritis" ⁵⁹, ²²⁵ as contrasted to secondary (hypertrophic) osteo-arthritis which may appear as the (radiologic) end result of many articular disorders, among them gout, late atrophic arthritis or gonorrheal arthritis in weight bearing joints

(The merits and demerits of the various terms for this disease were critically reviewed by Bauer and Bennett The term "hypertrophic" is not satisfactory because the hypertrophic changes are a relatively late feature of the disease, much later than its degenerative feature, nor is "hypertrophic" distinctive because many types of arthritis may show hypertrophic changes, for example, gout, hemophilia, Charcot joints, and so forth ¹⁷⁸ "Senescent" is a better term and is usually, but not always, appropriate, as the disease may, under unusual circumstances, appear long before senescence The word "degenerative" describes the primary phenomenon of the disease, is therefore peculiarly fitting and should be retained in the final designation "Arthritis deformans" is not distinctive since other forms (for example, atrophic) may be even more deforming The term "arthritis" has been objected to since there is little or no evidence of inflammation, hence, some have suggested "arthrosis" or "osteo-arthritis" which literally translated means "a joint full of bone" For various reasons therefore the term "degenerative joint disease" seemed preferable to Bauer and Bennett, until a term based on the ultimate etiology of the degeneration is known—Ed)

Incidence The studies of Bauer and Bennett, and others revealed that with each succeeding decade in life beyond the second, certain joints, especially knees and joints of the spine, show "degenerative arthritis" with increasing frequency so that the disease is pathologically universal after the age of 40 to 50 although it may be clinically apparent (that is, symptomatic) in only about 5 per cent

Clinical Features, Symptoms Of Haden and Warren's 50 consecutive cases the age incidence was from 34 to 69 (av 51) years in females, 34 to 58 (av 52) years in males Females were affected symptomatically five times as often as males (42 females, 8 males) In the cases which Bauer and Bennett studied at necropsy the patients had presumably never had significant symptoms although joints were often markedly affected It is common to find marked hypertrophic changes in one joint which is practically painless, and to find only slight radiologic changes in another joint which is very painful Why is one painful, the other not? Some believe the pain is due to superimposed infection According to Bauer and Bennett two

factors are responsible for pain. When marginal tissue is proliferating the periosteum may become elevated and cause pain. Once the marginal osteoid tissue ceases to proliferate and becomes calcified pain may also cease. The second factor in pain production is related to altered mechanics, occasional loose bodies, or the pinching of sensitive synovial villi. Gordon, however, blamed two other factors for the pain: (1) exposure of soft subchondral bone by cartilage destruction, and (2) presence of muscle spasm from the fibrositis which almost invariably accompanies hypertrophic arthritis. Buckley reminded us that patients with affected hips often have no pain therein, pain being referred to the knees which, in spite of normal motion and roentgenograms, are sometimes long treated for arthritis nonexistent therein.

Roentgenograms. The characteristic and differentiating radiographic features have been discussed. Spurs and exostoses, commonly present at muscle insertions, are but the "perfectly natural strengthening of ligaments at their insertions" and should not be misinterpreted as "osteo-arthritis"—a mistake often made even by radiologists, according to Gordon, to whom the essential roentgenographic feature of hypertrophic arthritis is the presence of osteoporotic areas in or about articular bone.

Pathology. The well-known pathologic features were reviewed by several^{194, 196, 200, 200}. In particular, Bauer and Bennett reviewed their development in the human and animal (spontaneous and experimental) forms of the disease.

Laboratory Data. Anemia is rare, only 4 per cent of Haden and Warren's 50 patients had hemoglobin below 75 per cent (11.5 gm per 100 cc). The neutrophile nuclear count usually does not show a left shift in hypertrophic arthritis as it does in atrophic arthritis. But such a shift was noted by Collins in 30 per cent of 11 cases of hypertrophic arthritis of hips and seemed to bear a definite relationship to bone cysts in hip joints. Accepting Ely's view that the cysts were areas of aseptic necrosis, Collins suggested that toxic absorption of some kind must proceed from these cysts, for when they were large, that is, with a large surface from which absorption might take place, the nuclear count showed a marked left shift, when cysts were small or scarcely apparent, the nuclear count was normal. Hartung and co-workers noted that the nonfilament count, which was always elevated in atrophic arthritis, was normal in 53 per cent, elevated in 47 per cent of cases of hypertrophic arthritis "perhaps due to associated rheumatoid disease or focal infection."

In contrast to atrophic arthritis the blood proteins are essentially normal in hypertrophic arthritis (Davis). The sedimentation rate was slightly elevated in 7 of Davis' 11 cases, normal in 80 per cent of Haden and Warren's 50 cases. Fasting blood sugar levels were usually normal, 22 per cent of the 50 patients had diminished sugar tolerance.

The cytology of synovial fluid in hypertrophic arthritis is strikingly dif-

ferent from that in atrophic arthritis. Collins noted a low absolute polymorphonuclear count in each of three cases, implying an absence of synovial inflammation. Total nucleated cells per cu mm were 210, 900, 5800, polymorphonuclears 4.5 to 14 per cent.

Contrary to the opinion that effusion is rare, Kling found in "osteoarthritis" periodic marked increases of synovial fluid with a high viscosity and a small number of cells, chiefly monocytes and synovial lining cells, indicative of synovial hypertrophy and hypersecretion.

Etiology and Pathogenesis No new views on etiology were expressed. The disease is presumably a degenerative process resulting not from one specific factor but from the wear and tear of increasing age, in other words, it is caused by life and the process of living.^{28, 59, 83, 181, 225} It is fostered by certain predisposing factors, hastened or made symptomatically active by other factors. Current writers differed only in the individual importance they ascribed to the different precipitating factor of heredity and constitution (that is, inheritance of vulnerable cartilage) or of the following accelerating factors: abnormal metabolism, circulatory deficiency to joints, various traumas, toxemia from infection, nutritional deficiency of articular tissues, gastrointestinal disturbances, exhaustion, alcoholism.^{181, 225} Some regarded the factor of trauma as the most important, and assigned no rôle to infection, metabolic disturbances or endocrine dysfunction (Bauer and Bennett). Others (Haden and Warren, Fletcher) stressed the importance of metabolic or nutritional factors.

Heredity and Constitution Anthropometric studies by Kovacs and Hartung indicated that patients with hypertrophic arthritis tend to have increased horizontal measurements, short thick necks, massive silhouettes, chest circumferences greater than abdominal. Ellman and Mitchell found slight. Kovacs and Hartung found no, psychologic differences between patients with atrophic and hypertrophic arthritis.

Patients may inherit the tendency to hypertrophic arthritis by inheriting tissues susceptible to degeneration (O'Brien). In cases in which hypertrophic arthritis comes on prematurely it is possible that premature senescence of cartilage has set in, cartilage aging faster than the rest of the patient's tissues. Thus Bauer and Bennett suggested that the type of cartilage one inherits governs in part the age of onset of hypertrophic arthritis and the rapidity with which it develops. If one inherits "good cartilage," hypertrophic arthritis may be long delayed in spite of the operation of the usual predisposing and aggravating factors. Considering the hereditary factor most important, Haden and Warren were unable to evaluate it in their patients because family histories of "arthritis" were so unreliable.

Trauma Several^{28, 208} regarded the dominant factor to be a variety of "microtrauma," that from obesity, overuse through occupation or recreation, malposture, congenital deformities or other mechanical defects. Gor-

don saw a close relationship between juvenile disorders—congenital hip disease, coxa plana, slipped epiphysis, Perthe's disease—and hypertrophic arthritis of hips late in life Of Haden and Warren's 50 patients with hypertrophic arthritis 62 per cent were an average of 25 pounds overweight, a source of physical strain to weight bearing joints Bauer and Bennett particularly stressed the factor of trauma Hypertrophic arthritis was readily produced by altering the apposition and weight bearing of joints in animals Certain patients were found to have marked hypertrophic arthritis in one joint subject to unilateral occupational or postural trauma, but none or very little in the opposite joint Thus hypertrophic arthritis may result in one knee more than its fellow, from loose bodies, knock knees, bow legs, intra-articular fracture, a pronated foot

Impaired Circulation Many assumed that hypertrophic arthritis may be due to deficient articular circulation, the circulation being impaired because of hypotension or, more often, of hypertension and arteriosclerosis Buckley⁵⁸ noted the frequency of osteo-arthritis of hips in horseback riders due possibly not to trauma but to obstruction of the blood supply through compression of the artery of the ligamentum teres owing to extreme abduction of the hip According to Gordon the disease occurs in those whose vascular system is beginning to deteriorate, not necessarily generally, but locally, in the region of one joint or one limb "This vascular deterioration leads to a relative malnutrition and consequent degeneration of structures whose blood supply is defective, and this is the primary cause of osteoarthritis"

(No data proving these ideas were given—Ed)

Of Haden and Warren's cases none of the 8 males and only 24 per cent of the 42 females had a systolic blood pressure more than 140 to 145 mm of mercury Nevertheless they concluded "the frequent observation of calcareous deposits in arteries, the common finding of arterial hypertension, and the well-known gradual decrease in capillary bed with age, all emphasize the circulatory factor"

Monroe and Walcott compared 257 patients with hypertrophic arthritis to "normals" of similar age and noted the following respectively cardiac enlargement in 18 per cent of arthritic patients, in 4 per cent of controls, hypertension respectively in 39 per cent and 8 per cent, arteriosclerosis in 16 per cent and 18 per cent, varicose veins in 15 per cent and 8 per cent They concluded that cardiovascular disease occurs with increased frequency in patients with hypertrophic arthritis

(The conclusion does not seem justified Arteriosclerosis was not present in an unusual number of cases—Ed)

Bauer and Bennett admitted that vascular deficiency might be a factor but in the study of knee joints of persons with hypertrophic arthritis who died at various ages arteriosclerosis was not found to be an important feature

Endocrine Disturbances Some⁴¹⁵ vaguely incriminated "an endocrine

imbalance of thyroid and ovaries," but, as Bauer and Bennett stated, no proof exists that endocrine disturbances alone ever produce the disease. Of Peer's 28 cases the metabolic rate was below — 9 in 60 per cent, below — 14 in 3 per cent (below — 19 in 2 cases)

(No normal controls of similar age were studied. His results in the atrophic group were essentially similar—Ed.)

Of Haden and Warren's cases metabolic rates were (slightly) above normal in 16 per cent, below normal for their age in 84 per cent, the average decrease below normal was 15 per cent.

(Most patients were given only a single determination. The analysis as given was not complete enough for conclusions—Ed.)

Miller believed that endocrine disturbances may cause the obesity but not the arthritis, except indirectly.

Metabolic Disturbance Peers found no disturbances of sugar metabolism of etiologic significance. Indoluria was noted by Forbes and associates in 10 of 13 cases of hypertrophic arthritis as well as of atrophic arthritis. Because of this and because five of eight patients treated with a high sulfur, low carbohydrate diet "improved," a disturbance in hepatic function and in sulfur metabolism was suspected. Six patients studied by Rinehart, Greenberg and Baker showed no evidence of vitamin C deficiency, indeed their plasma ascorbic acid content was high 0.90 to 1.34 mg per 100 c.c.

Factor of Infection Patients with hypertrophic arthritis present little direct or indirect evidence of infection. Practically none of the patients of Haden and Warren had been seriously ill within five years of the onset of arthritis. Only 42 per cent had *foci of infection*, a small per cent for the age of the group. *Blood cultures* from 39 patients of McEwen, Alexander and Bunim were positive (all for green-producing streptococci) in 26 per cent, a finding considered incidental. Patients with hypertrophic arthritis do not often possess *agglutinins* either to hemolytic or green-producing streptococci in significant titer. McEwen, Alexander and Bunim found agglutinins to hemolytic streptococci in none of 46 patients. Hartung and associates noted agglutinins to green-producing or hemolytic streptococci practically never (in a few cases to one green-producing strain only). Agglutinins to hemolytic streptococci were found by Goldie and Griffiths in a dilution of 1:100 in only 10 per cent, 1:200 in 5 per cent, 1:400 or more in none, to green-producing streptococci in dilutions of 1:100 in 5 per cent, in higher dilutions never. *Precipitins* to hemolytic streptococci were present in serum of 10 per cent of 21 patients²⁴³. They were present in 18 of the 30 cases of McEwen and associates (reaction slight in seven, definite in seven, marked in four, very strong in none).

Antistreptolysins More than 100 units were not present, according to McEwen and associates (46 cases), Dawson and Olmstead (24 cases), Goldie and Griffiths (30 cases). *Antifibrinolysins* were absent in all of

Stuart-Harris' six cases, in 62 per cent of 13 cases of McEwen and associates (they were weakly present in 38 per cent) *Skin tests* with hemolytic streptococci were negative in 100 per cent, those with green-producing streptococci were negative in 97 per cent of the 30 cases of Goldie and Griffiths

In spite of this mass of negative evidence others believed that infection might play some rôle Poynton⁴³⁹ stated that osteo-arthritic changes may be produced in animals by injecting streptococci intravenously Irons had seen Heberden's nodes become acutely tender, red and swollen following a respiratory or other infection According to Holman the absence of a pathologic reaction of inflammation does not entirely rule out the rôle of infection

Treatment Since cartilage has little or no capacity for repair, little can be done to replace significant cartilaginous destruction or to "cure" the disease But much can be done to lessen pain, perhaps to stop or slow the progress of the disease by correcting accelerating and causative factors^{28, 58, 225} Measures should be (1) to relieve strain and trauma of all sorts, (2) to check factors which favor degeneration Given a chance, nature will repair many of the cartilage defects after a fashion (with fibrosis), the repair at best is a poor substitute for the original cartilage but often the joint will be as useful as ever (Ghormley) Some will be limited, a few will become markedly limited True ankylosis does not occur but "artificial ankylosis" may result from interlocking osteophytes Reassurance is one of the most important features of treatment, patients must be told they are not headed for crippledom and a life of invalidism

Many of the measures indicated in atrophic arthritis, particularly the more strenuous ones, are not suitable in hypertrophic arthritis According to Bauer and Bennett, there being "no evidence favoring infectious, metabolic or endocrine theories, these patients should not be subjected to wholesale removal of foci, administration of endless sera and vaccines, endocrine therapy, colonic irrigations, hyperpyrexia, weird dietary regimens, etc" However, Pemberton believes that measures effective in atrophic arthritis are equally applicable in hypertrophic arthritis

Reduction of trauma of whatever type is indicated Bed rest is often very useful, but rest should not be complete, joints should be moved through their full range of motion frequently^{28, 58, 431} Bandages or caliper splints may provide special rest for hips or knees, and corsets or braces for the back⁵⁸ However, "it is often difficult to persuade the conservatively minded and short-tempered old lady or gentleman to harness themselves with 'this piece of damned iron-mongery'" (Gordon)

Obesity being a common source of trauma, weight-reduction diets were generally advised^{28, 58, 225} Two patients, given a raw vegetable diet, noted some relief at first, relapses later²³⁷

Massive doses of vitamin D alone were given by Livingston to three patients, in conjunction with fever therapy to four other patients, two of the former and all of the latter were "improved"

Some saw no indication for removal of foci,²⁸ others removed them conservatively for general reasons. Gordon wrote, "If the physician can persuade himself that a focus of infection is contributing to the general degenerative process, then such a focus should be removed so long as the strain involved in its removal does not prove too much for the frequently elderly and sometimes feeble person, so that he dies of his cure." Kovacs gave various vaccines in 42 cases; improvement was noted in only a few, some patients were made worse. Foreign-protein therapy seemed useless.²⁰⁸ Cases of hypertrophic arthritis were considered suitable for bee-venom therapy by Mackenna [no statistics given].

Iodine was prescribed by Buckley, given orally or intramuscularly as lipiodol "to provide a reservoir of the drug from which absorption into the circulation continually goes on with definite relief of pain and stiffness in many instances." Intramuscular injections of sulfur gave "considerable recovery" to only two of Krestin's five patients. Sulfur, given in a high sulfur diet, "markedly improved" five of eight patients of Forbes and associates.

Gold therapy is "useless," "unsuitable" in hypertrophic arthritis^{14, 18, 538}. Only two of eight patients of Phillips noted subjective improvement. However, Slot noted "beneficial results" in some cases, and 13 of Oren's 22 patients "responded well." Gordon regarded "the precious metal more obviously beneficial to the physician than to the osteo-arthritic patient." Histamine injections were recommended by Eastwood and Shanson, histamine ionization by Mackenna, 9 of whose 13 patients noted reduction of pain and stiffness.

Roentgen-ray therapy was considered useful^{164, 183, 477}, it is presumably analgesic, reduces congestion, and causes absorption of pathologic fibrous tissue.

(Very few, if any, controls were used in the evaluation of most of these forms of treatment, details given were very meager—Ed.)

Fever Therapy Of 64 patients treated by Davison, Lowance and Barnett, 44 were "markedly relieved," 13 "definitely relieved" and 7 not relieved. To the "great surprise" of Warren and Lehmann "several cases" of hypertrophic arthritis were "markedly relieved over a long period of time" after a single artificial fever at 40.5° C for 4 hours. Others considered cases of hypertrophic arthritis unsuited for fever therapy. The patients do not react well, and during such therapy may develop "delirium and other terrifying states"^{405, 406}. According to Hench's summary of reported results in 74 cases, only 5 per cent of patients became symptom-free^{249, 250}.

Physical Therapy The usual varieties were recommended. Several favored hydrotherapy,^{58, 104, 183, 208} especially the use of warm pools, it relieves the muscle pains and spasm of associated fibrositis. Relative merits of different forms were described^{58, 148}. Patients with hypertrophic arthritis are particularly in need of simple methods for home physiotherapy which

Coulter described Short-wave therapy gave temporary relief in a few cases ^{506, 582}

Sympathectomy This is not indicated in senescent hypertrophic arthritis according to Adson. However, Young noted "rapid amelioration of pain" and "substantial improvement" in motion of the hip of a 62 year old woman who was so painfully crippled that she requested the procedure.

(Because of temperature gradients existing in legs, skin temperatures about hips and thighs are altered but slightly after sympathectomy. It is unlikely that in Young's case relief was due to sympathectomy per se, it was probable that from any operation, the effect of anesthesia, bed rest, convalescence—Ed.)

Bone Puncture "Osteoarthritis and rheumatoid arthritis belong to the same type of disease" according to Mackenzie, who obtained "worth while improvement" by bone puncture in 80 per cent of 106 cases (types not separately analyzed). This was discussed under the treatment of atrophic arthritis. Simpson and Henderson noted "definite benefit" in seven of twelve cases of osteo-arthritis of hips (for more than six months at time of follow-up) in which bone drilling of the neck of the femur was done, only one of ten patients subjected to trephining by Ducker noted improvement. Contrary to Mackenzie's experience, Ducker noted exacerbation, not relief, of symptoms of osteo-arthritic hips after spontaneous fracture of femurs.

Orthopedic Procedures Indications for cheilotomy, osteotomy, arthrodesis, arthrotomy, acetabuloplasty, and plastic procedures on the head of the femur were given ^{178, 255}. In selected painful cases of monarticular hypertrophic arthritis of hips, Malkin noted good results from femoral osteotomy. Arthrodesis seemed most satisfactory to Gordon.

For the relief of pain in hips Slot recommended epidural injections of 1 per cent procaine.

BACKACHE

There have been two schools of thought as to the cause of backache. "The cause of most backaches is anywhere but in the back." According to this, the older school, pains in the back most often arise from distant infection or from gynecologic or urologic diseases. According to the newer or "mechanistic school," the cause of most backache is in the back (Milliken). Backaches are described as of medical, orthopedic, urologic, neurologic or gynecologic origin. Data on the commonest causes of backache are difficult to obtain. Published statistics must be interpreted in the light of the writer's specialty. The internist, orthopedist and gynecologist will differ on "the commonest cause." Kuhns considered trauma, faulty posture and fatigue the most frequent causes. According to Albee myofascitis is the commonest cause, Hartung considered most backaches due, not to one factor, but to a combination of postural, arthritic, traumatic and congenital factors.

Postural Backache Milliken believed that one may "assume the case to be postural if no other pathology is found" on careful examination. According to Brown, in the drooped position of the thorax seen in faulty body mechanics it is possible to get pressure or stretching of the intercostal nerves with radiating pain. This pressure may come from acute or chronic inflammation due to strain of the costovertebral or costotransverse joints. According to Henry, poor abdominal musculature permits increased sacral inclination which, whether it is the cause or result of faulty body mechanics, throws a strain on the lumbosacral ligaments and articulation. According to Hartung, exaggerated lumbar lordosis is the cause of most postural defects. Indiscriminate exercise is valueless, exercises recommended are those which tilt the front of the pelvis up and the back of the pelvis down.

Sacro-Iliac and Lumbosacral Strain Sacro-iliac strain and dislocation as causes of backache have been greatly exaggerated^{241, 307, 370}. The pathogenesis, symptomatology and treatment of lumbosacral strain and its differentiation from sacro-iliac strain were reviewed^{374, 375}. "Sacrarthrogenetic telalgia" was the formidable term applied by Pitkin and Pheasant to "the typical syndrome of pain which originates in the sacro-iliac and sacrolumbar articulations and their accessory ligaments". Under this heading were given a study of referred pain, sacral mobility, alternating scoliosis, differential diagnosis of "sacrarthrogenetic scoliosis" and treatments used in 1000 cases of low back pain.

"Post-Operative Backache" This is most often caused by the inadequate support of lumbosacral muscles in a sagging bed. Berman prevented it "easily" by incorporating a new "movable semicircular spring unit" in regular hospital beds.

Uterine Displacements These often cause backache, according to Dicks. "Backaches above the lower lumbar and sacral regions have no direct relationship with pelvic disease". However, Holt believed pelvic disease was a rare cause of backache. "The backache most frequently associated with kidney conditions is felt in the costo-vertebral angle particularly over the superior lumbar triangle"⁴⁴⁰.

Myofascitis An infectious or toxic inflammation of muscles and tendons of the lower back is one of the commonest causes of low backache according to Albee. Kuhns considered it a rare cause of low back pain. Lumbago represents acute or chronic myofascitis^{150, 151, 241}.

Other causes of low back pain and secondary sciatica were discussed: the rôle of congenital anomalies such as spondylolisthesis, lumbosacral transitional vertebrae, posterior displacement of the fifth lumbar vertebrae, and so on^{27, 206, 241, 305, 375}; coccygodynia³⁰⁵; contracted iliotibial bands and fasciae producing low back pain and sciatica^{413, 414}; diseases of intervertebral disks and conditions secondary thereto^{16, 146, 227, 256, 352, 373, 404}.

Clinical and radiologic features of *neoplastic diseases* of the spine were given^{186, 216, 365, 459}. Fray discussed radiologic differences between infection

and malignancy in cases in which there is a dorsal paravertebral mass. Important radiologic features of malignancy were preservation of articular plates in the presence of collapse of the body, slight or no narrowing of disk spaces in cases of marked collapse, absence of wedging resulting in little or no kyphos, diffuse increase in bone density, and involvement of vertebral appendages. Normal roentgenograms may be obtained in the presence of metastatic foci of malignancy, for the latter are visible in roentgenograms only when large enough to produce a definite contrasting shadow or when marked osteosclerosis occurs about the metastasis.²¹⁰ Cases of vertebral involvement in Hodgkin's disease were reported.⁴⁵⁹

Diseases of Intervertebral Disks The muscular, ligamentous, neural and osseous components of the spine are so closely related anatomically and physiologically that no one part lives unto itself alone. In last year's Review we gave a detailed presentation of the "newer anatomy of the spine," the physiology and pathology of intervertebral disks and posterior facets, and diseases secondary thereto. Current reports contain little different, several^{227, 289, 461} reviewed the subject. Certain changes in intervertebral disks may be quite unrelated to a patient's complaint and a given backache must not be incautiously ascribed to such changes found in roentgenograms. Many variations in disks do occur but the consensus of opinion seems to be that many disk changes are of little significance.²⁵⁶ According to Bailey and Taylor herniation of the nucleus pulposus or the disk usually occurs into a vertebral body, rarely results from sudden trauma, is usually a degenerative process from wear and tear, and is seldom of clinical significance. Herniation of a disk in any other direction than into vertebral spongiosum is often related to sudden trauma and may cause pressure on the spinal cord.

Recently narrowed or ruptured disks have been considered the cause of a wide variety of complaints—compression phenomena, sciatica without neurologic changes, and pains and aches of varying severity about the lower back. Sashin's patients with narrowed disks complained mainly of dull aching pains in the lower back, often of sciatica. They usually gave a history of mild injury, a slight fall or sudden twist. They walked guardedly with stiff, often tilted spines, and had lumbosacral and gluteal tenderness. Lateral and oblique radiographic views of the spine revealed the narrowed disk. Sashin's treatment aimed to reestablish normal lumbar lordosis and to support the spine by rest in a plaster bed or jacket. No manipulation was used.

(Four illustrative cases were given. Narrowed disks were present but the evidence seems insufficient for us to conclude that symptoms in these four cases were actually due to the narrowed disks. Detailed results of treatment were not given.—Ed.)

Narrowing of a disk does not necessarily indicate a protruded disk, narrowing may occur from degeneration and fibrosis of the disk without protrusion, and posterior protrusion may occur without narrowing. In-

deed, according to Camp, narrowing of the intervertebral space at the site of a protruded disk occurs in only a small percentage of cases. Therefore ordinary roentgenograms are only suggestive and of limited value in the diagnosis of herniated disk. In Love's series of cases in which operation was performed, protrusion occurred in any region of the spine, especially the lumbar region. Commonest symptom was sciatic pain. The diagnosis was easy in the presence of neurologic findings: motor weakness, sensory loss, signs of a compression-level in the cord. The diagnosis is difficult in the presence of pain only, with no neurologic findings, it then depends on fluoroscopic and roentgenographic examinations of the spinal canal after subarachnoid injections of lipiodol. One should not do this to all patients with obscure back pain. Love advised it only for the following patients: (1) those whose pain follows the distribution of one or more spinal nerve roots for a considerable period of time and who have not been notably relieved by orthodox conservative treatment, (2) those whose cerebrospinal fluid contains more than 40 mg total protein per 100 c.c. fluid and reacts positively to a test for globulin (Love admitted, however, that protruded disks with compression phenomena do occur in patients with normal or even low values for total protein in spinal fluid), and (3) those who demonstrate a "reversed Queckenstedt test." This is the most important of all criteria for the use of lipiodol intraspinally, and at times, according to Love, gives the only real clue to the cause of the trouble. [The technic and interpretation of the test were given.] The absence of an increase in the manometric reading and an unbearable pain response provides a pathognomonic sign of a mass pressing on caudal roots. If the protruded disk corresponded to the level of the root pain complained of, then and only then was surgical treatment (laminectomy) performed, for disks can herniate without causing pain.

Intervertebral disks may be injured by lumbar puncture, with subsequent production of symptoms (Pease, 1935). Milward and Grout noted five patients operated on under spinal anesthesia, who at varying intervals (immediately, three weeks, five weeks, four months, six months) after operation, complained of severe pain in the back, occasionally in the lower limbs. They could not stand or sit fully erect. Spasm of lumbar muscles and marked tenderness over one or more lumbar vertebrae were present, in one case, with transient urinary retention. Roentgenograms (well illustrated) showed a rapidly progressive lesion, a progressive arthritis localized to one intervertebral joint, loss of joint space, new bone formation between edges of adjacent vertebrae. Milward and Grout favored Pease's explanation: the needle puncture traumatized the annulus fibrosus with rapid (in children) or slow (in adults) escape of the nucleus pulposus and the subsequent development of localized arthritis.

An unusual case of herniation of the intervertebral disk between the sixth and seventh cervical vertebrae complicated by a localized staphylococcal in-

tection and fatal compression of the cord was reported by Dickson. Hadley again described the possible results of degeneration of disks: thinning of disk, closer approximation of vertebral bodies producing (1) a localized kyphosis if posterior articulations do not slip past one another, (2) apophyseal subluxation with reduction in the size of the intervertebral foramina and production of radiculitis, or (3) actual bony impingement between the tip of the articular process and the pedicle above, or the lamina, below (all illustrated in the report). Hadley described a new point in the radiologic diagnosis of apophyseal subluxation: distortion of an "S-line."

General Measures for Low Back Pain Measures discussed were the institution of rest, relaxation and support for the spine, the use of proper beds, strapping, heat, massage, belts, corsets, braces (not to be worn too long), proper shoes, exercises to improve body posture and to strengthen abdominal and spinal muscles^{256, 303, 320}. Correct treatment presupposes a correct diagnosis, which is not an easy matter, and can be made only after a thorough physical and radiologic examination. Lewin in particular described with diagrams and photographs the various physical signs and tests useful in differentiation of lumbosacral, sacro-iliac and adjacent diseases. In special cases manipulation for low back pain is most useful^{241, 305, 341}. The indications, contraindications, technic and after-care of manipulation were given in detail by Lewin.

Epidural injections of procaine seemed of little value to Kimberley. Special indications for facetectomy, fasciotomy, and lumbosacral fusion were given^{206, 338, 370}.

SCIATICA

Classifications of sciatica were reviewed³⁶, Douthwaite used a familiar one: (1) sciatic neuritis, acute or chronic—(with neurologic changes), (2) central sciatica, acute or chronic (as a rule without neurologic changes) often called by others "secondary sciatica" or "sciatic pain". The latter is generally secondary to disturbances in the lumbosacral region. "Real sciatic neuritis" with neurologic changes in sensation and reflexes, and muscle atrophy in thigh or calf are rare, according to Henry, who regarded the commonest form of sciatica to be usually a symptom, not of nerve trunk disease but of hamstring spasm or irritation of the piriformis muscle from arthritis or other cause. Douthwaite wrote of the possibly serious significance of bilateral sciatica: "Any patient with sciatic pain in both legs must be suspected of a central—e.g. vertebral, spinal or pelvic disease, not forgetting the very real possibility of a cauda equina tumor." All other examinations including that of cerebrospinal fluid must be negative before accepting a diagnosis of "simple" bilateral sciatica.

Causalgia (neuralgia characterized by intense, local, burning pain) rarely affects other than the median nerve, the tibial portion of the sciatica, and less often the ulnar nerve. Karnosh reported two cases which supported the view that sciatic causalgia results from ischemia of the nerve trunk.

Ten days after striking his right gluteal region and developing a hematoma, a patient began to complain of paroxysmal burning, dragging pain in a heel, extending into the calf. At exploration it was found that the nutrient artery to the sciatic nerve had been severed. Another patient developed sudden burning paresthesia of a foot while at work. For reasons given a diagnosis of sciatic causalgia from thrombosis of a nutrient artery was made.

Treatment The usual measures of heat and rest were advocated. For "rheumatic sciatica," polyvalent streptococcal vaccine suspended in oil (lipovaccine) was injected by G. L. Scott into perineural tissues and "into the fibrositic areas which seem always to be associated with neuritis of this type", of 15 patients 12 were rapidly "cured", two were "benefited", one was not.

Epidural injections of normal saline through the sacral hiatus seemed to Wallace to be "far the best treatment for chronic sciatica" (No results were given). Subarachnoid injections of alcohol were used by Goff to relieve "sciatic neuralgia". Although there is some danger of motor depression and paralysis, this rarely results, according to Goff, because motor nerves are myelinated and well protected, offering great resistance to the caustic action of alcohol. Of 20 patients with "intractable pain" so treated 15 were "relieved at once", the other 5 were "relieved the same day". A few had a return of pain within the first two weeks but at the end of three weeks 18 of 20 were "entirely relieved". Eight had temporary urinary retention.

(We believe that such injections are not without danger except when done by experts, they constitute symptomatic treatment only and should only be done under special circumstances in cases unrelieved otherwise—Ed.)

Bee venom gave relief in some of Mackenna's cases of "sciatic neuritis" (Very meager details were given). Taylor-Pergalley recommended "labile diathermy"—one electrode kept in motion over the area treated.

Manipulation may bring dramatic relief in certain cases of secondary or central sciatica.^{150, 341} Lewin described indications and methods in detail. Ober gave further results from his treatment of sciatica by incision of contracted iliotibial bands and fasciae. A new skin incision was used. Forty-two patients were treated. 23 were cured, 10 were improved, 9 not improved. A few noted relief "at operation". The majority noted relief of sciatic pain beginning the fifth to the tenth day after operation. "The lame back clears up in from six weeks to six or eight months but occasionally lasts longer". The rationale of the procedure was given. Shortening of the iliotibial band and its fascial expansion causes an abduction contracture of the femur, "resulting in a tremendous leverage action on sacroiliac and lumbosacral joints. Any contracture of the fascia lata must exert muscular pressure on the sciatic nerve which lies beneath the gluteus maximus where it emerges below the piriformis". According to Ober many cases of lumbosacral, sacro-iliac and sciatic pain are so caused. Nutter noted relief

in several cases in which the nerve was explored and iliotibial bands sectioned. The mechanism of relief was uncertain because in some cases tight bands were not found and no irritation of the nerve trunk was seen although relief was obtained. According to Cave "it is the correct diagnosis of iliotibial contracture and not the Ober operation that is difficult." Diagnostic tests were described. Results of fasciotomy in six cases were two cures, two "fair results," one "poor result," one "failure." Of 32 patients treated by a colleague of Ober, results were "perfect" in 27 per cent, "good" in 34 per cent, poor in 39 per cent.

COMMON TYPES OF SPONDYLITIS

Two clinical types were recognized, corresponding to two distinct pathologic types (1) atrophic spondylitis, (2) hypertrophic spondylitis. "Atrophic spondylitis" is synonymous with "rheumatoid spondylitis," and "spondylitis ankylopoietica" or "ankylosing spondylitis." Most current writers were unwilling to subdivide atrophic spondylitis further and considered the so-called subvarieties (a, spondylitis ossificans ligamentosa or Marie-Strumpell type, b, spondylitis muscularis or von Bechterew type) minor variations of one disease. Hypertrophic spondylitis is synonymous with osteo-arthritis of the spine, spondylitis osteo-arthritis.

Details of the clinical, radiologic and pathologic differences of these two main types (and of the subvarieties of the first type) were given in the second review and have been given again ^{203 269 505, 535}

Atrophic spondylitis generally appears in men below 40 years of age, exhibits an increased sedimentation rate and other nonspecific signs of an infection, involves sacro-iliacs early, and stiffens the spine chiefly by a process of ligamentous calcification. Hypertrophic spondylitis generally appears after the age of 45 years in either sex, is not associated with the chemistry of infection, does not involve sacro-iliacs early or characteristically (although they may be affected), produces moderate stiffening by formation of osteophytes which only occasionally coalesce to form isolated bridging, not diffuse regions of ankylosis.

Egyptian mummies exhibited only atrophic arthritis according to some (Jones, 1907 and 1908, Smith and Jones), both atrophic and hypertrophic arthritis according to others (Moodie, 1923, Ruffer, 1926). Shore's examination of spines of predynastic Egyptians would indicate that several types of spondylitis were extant, tuberculous, possibly staphylococcal and other definitely microbic types, also atrophic and hypertrophic types. One, perhaps two, of his seven specimens showed ossification of perivertebral fibrous sheath. Specimens of localized and generalized hypertrophic spondylitis were noted.

ATROPHIC SPONDYLITIS

Three views were expressed that atrophic spondylitis (rhizomelique) is (1) identical with atrophic arthritis elsewhere and is merely atrophic arthritis in the spine ^{505 535}, (2) a separate disease but "somewhat like" or

"having much in common with," atrophic arthritis^{58, 203}, (3) not one disease but a pathologic end result of several diseases^{83, 369}. Much like atrophic arthritis elsewhere, according to Buckley and Golding, atrophic spondylitis differs from the former in several particulars: ligamentous calcification extending some distance from joints as seen in spine, rib articulations and hip joints, is not a feature of atrophic arthritis, the age and sex incidence of the two are dissimilar, the spine is involved seldom in atrophic arthritis, and the small joints rarely in spondylitis, remissions are much commoner in spondylitis than in atrophic arthritis. Miller³⁶⁸ viewed atrophic spondylitis as a pathologic but not a clinical entity. "Ankylosing spondylitis is infective in character and, unlike rheumatoid arthritis of extremities, may be produced by a variety of microorganisms, and develop as a complication of various diseases, such as rheumatoid arthritis, gonorrhea, typhoid fever, bacillary dysentery and influenza, one case has been reported after undulant fever. Without regard to the nature of the infective agent, the pathologic changes are identical." Again he wrote³⁶⁹ "one must bear in mind that in only a small percentage of cases is spondylitis ankylopoietica due to the infection responsible for rheumatoid arthritis. The gonococcus is responsible in a large percentage of cases." The usual absence of streptococcal agglutinins suggested to Cecil that "spondylitis deformans is not always referable to the streptococcus, this would fit in with our clinical observations, for one sometimes sees this form of arthritis coming on after gonorrhea or even after typhoid fever."

(We cannot accept the view of Miller and Cecil. Admitting that the cause of atrophic spondylitis is unknown, we know of no proved cases of gonorrheal or typhoid spondylitis with the chronic clinical course and pathologic reactions of atrophic (ankylosing) spondylitis. Proved cases of gonorrheal arthritis are not chronic and progressive but practically always acute or subacute in onset and course. Typhoid fever produces a localized spinal abscess with resultant localized hypertrophic reaction. The reported manifestations of undulant fever in the spine have not resembled the clinical or pathologic features of chronic atrophic spondylitis—Ed.)

A new series of 124 cases (106 males, 18 females) was studied by Golding. The disease was not more common in manual than in the sedentary workers, 73 per cent of these patients led sedentary lives. Many were free of foci of infection. Blood calcium was high normal. Only nine patients gave a history of gonorrhea. In early cases with sacro-iliac changes only, sedimentation rates were generally elevated (5 to 123 mm) but on the average not as high as in those with sacro-iliac and spinal radiologic changes in which rates were 9 to 110 mm. Golding and Scott repeated Scott's ideas on pathogenesis. All of Scott's 110 cases and of Golding's 124 cases (they may have been overlapping cases as the two writers collaborated) showed radiographic indication of bilateral "infection" of both sacro-iliac joints ("sacro-ilitis") usually with ankylosis. These changes were regarded as long antedating any spinal involvement. According to Scott and Golding the sacro-ilitis generally commences several years before

any symptoms referable to the back or even to the sacro-iliac joints themselves, and has "not therefore been clinically recognized as a manifestation of spondylitis adolescens" (Scott's term for the disease) The patient's course is presumably as follows He develops vague spells or more definite attacks of "wandering pains" across shoulders, down arms, round the ribs, and finally down the thighs, pains of a fibrositic character recurring over several years with free intervals This is the "pre-spondylitic phase," the pains of which are referred to muscles or near joints and are occasionally associated with a resolving synovitis of peripheral joints There may be "tightness of chest" and (according to Golding) pains in thighs and buttocks "Pain in the back or sacro-iliac region is not present at this period" ⁴⁷⁸ Presumably the patient is insidiously developing sacro-ilitis which is apparently relatively symptomless until the disease is well advanced It may cease any time and spondylitis never develop, or it may progress No spinal symptoms (rigidity, pain) are complained of until sacro-iliac ankylosis has already begun Of Golding's 124 patients, 33 presented sacro-ilitis alone, 91 had spondylitis with advanced sacro-ilitis Scott therefore regarded the sacro-ilitis the source of the spinal infection "If this source of infection can be removed or adequately dealt with, spondylitis in the young adult will cease to exist" In three early cases of sacro-ilitis trephining was done pus was absent, cultures were contaminated, the bone was grossly diseased, the operation "certainly proved beneficial" Scott recommended more conservative therapy—wide field radiation with roentgen-rays of medium length Results were "so encouraging that the method is being adopted in all cases seen early enough" Several patients so treated were free of symptoms, one for five years

Weil also held that the fibroid calcification (ligamentous ossification) is a defensive affair secondary to sacro-iliac arthritis and arthritis of the posterior vertebral articulations It is possible, "by recognizing and treating this arthritis in the early stages, to prevent the development of its subsequent lesions, and to reduce or do away with the painful invalidity resulting from it" Prevention and early recognition, according to Scott, necessitate an early radiographic examination of sacro-iliacs "in every case where recurrent attacks of muscular rheumatism extending over a number of years, occur in the young adult"

(Scott has not yet proved his hypothesis Even were the sacro-ilitis the "focus of infection" for the spine, which is not proved, what is the source of the sacro-iliac "infection," by what means does it spread to the spine? So far its infectious nature is only a fairly logical presumption Even were one to discover the early lesion it has not been shown that the therapy of Scott, Weil or any other will consistently check it Final results of Scott's therapy after five years or more will be awaited with interest Others have noted early and frequent involvement of sacro-iliacs in atrophic spondylitis but have not considered it the consistent etiologic precursor of spondylitis In their study of 11 cases of at least two years' duration each, Taylor, Ferguson, Kasabach and Dawson noted calcification of spinal ligaments and ankylosis of intervertebral facets in 100 per cent, the latter was "almost

invariably" (but not invariably) accompanied by sacro-iliac obliteration. Some of us do not recall seeing a case of atrophic spondylitis with radiographically normal sacro-iliacs. Others of us believe that cases of undoubted atrophic spondylitis with radiographically normal sacro-iliacs are occasionally seen. One of us, J. A. K., examined two skeletons with typical spinal ankyloses from atrophic spondylitis in which sacro-iliacs were not involved—Ed.)

Pathology Miller noted one of the reasons for the unusual pathologic reactions of atrophic spondylitis as compared to atrophic arthritis elsewhere in the latter situations the disease first involves synovia. Since intervertebral disks do not have synovia, atrophic arthritis cannot reproduce in disks (the big "joints" of the spine) the same pathologic reaction it produces in peripheral joints. However, as the disease attacks the "true joints of the spine" (the facets or articulations of the transverse processes, which possess synovia), the same pathologic reactions are presumably produced here as in peripheral joints. (Studies on the pathologic reactions in the true joints of the spine in spondylitis are needed—Ed.)

Treatment Scott's treatment was noted. Others advised the usual treatment as for atrophic arthritis elsewhere with certain additions: extra rest in bed on a proper bed in a proper position, breathing and other exercises, plaster shells and braces to prevent and correct deformity. Without giving results, Buckley recommended Ponndorf's vaccine B, roentgen-ray therapy, and gold. Baker considered gold useless. The usual physiotherapeutic methods were advised. Speeding regarded short-wave therapy dubiously. Histamine by injection¹⁵⁷ or by ionization³⁶⁰ was recommended for analgesia. Stecher's six patients received 19 fever treatments with considerable analgesia but no increased mobility. Improvement had lasted one year in one case, six months in five cases. Hartung recommended paravertebral injections of procaine or alcohol, or epidural injections for root pains which some considered common,³⁶⁹ others rare.⁵⁹

HYPERTROPHIC SPONDYLITIS

A localized hypertrophic spondylitis may be the pathologic or radiologic end-result of several causes: trauma, typhoid, undulant fever, or other infection. In the clinical sense, "hypertrophic arthritis" is an entity synonymous with hypertrophic arthritis elsewhere. We²⁴⁷ previously gave a detailed account of the relationship between degenerative changes in the intervertebral disks and hypertrophic spondylitis. Miller summarized this relationship developed by Schmorl and others. The disease is the result of primary degenerative and secondary hypertrophic reactions due to the wear and tear of traction and trauma.^{58, 369}

Considerable attention is being paid to its neurologic manifestations. Some³⁶⁹ are "very positive" that root pains are not directly due to osteophytes. However, the generally accepted cause of root pains is that nerve roots are pressed on by osteophytes in the spinal canal or at the point of emergence from the foramina.⁵⁹ Such a radiculitis was present in 30 cases

of cervical hypertrophic arthritis reported by Hanflig. Pain and other sensory, and sometimes motor, disturbances were produced most often about the shoulder girdle, less commonly at the back or side of the neck and down the arm, occasionally in the precordial region. Hanflig's patients complained of pain of variable severity, sometimes "agonizing," sometimes numbness and weakness of hand, muscle incoordination, at times some muscle atrophy, loss of position sense, even absent reflexes and flaccid paralysis. Varying degrees of muscle spasm and cervical rigidity were noted and rotation of the neck often sharply accentuated the complaints. The cases were frequently misdiagnosed arthritis of shoulder, bursitis, toxic neuritis. In every case cervical hypertrophic arthritis was present and shoulder joints were negative. In each case nerve symptoms corresponded to the cervical segment involved with osteophytes.

The variability and type of pain can be understood from the following. The fourth cervical segment supplies the sensory innervation over the top of the shoulder, the fifth supplies the sensory innervation of the outer surface of the arm between the shoulder and elbow. The deltoid muscle is supplied by nerve fibers derived from the fifth and sixth cervical segments. The pectoralis major and minor are innervated by the medial anterior thoracic nerves (which come from the eighth cervical and first thoracic spinal segments) and the lateral anterior thoracic nerve (from the sixth and seventh cervical segments). Although the latter two are motor nerves and do not carry skin sensory fibers, they can possess protopathic sensations, so that irritation of them may produce diffuse yet definite pain referred to the terminal portion of the nerve. When the anterior roots of spinal nerves are sufficiently involved, there may even be muscle incoordination, loss of position sense, absent reflexes or flaccid paralysis.

The same symptoms which Hanflig noted in cervical hypertrophic arthritis were noted by Turner and Oppenheimer in 50 cases with narrowed cervical intervertebral disks (the precursor of hypertrophic changes) whether cervical hypertrophic arthritis was present or not. Chief complaints were pain in some part of the shoulder girdle, neck, arm, hand, back or precordium, occasionally weakness or inability to perform certain movements (writing, combing hair, fastening buttons, grasping or steering automobile wheel, elevating hand above head "as in the Fascist salute"). Some complained of tingling fingers, pain on turning neck, or on walking or riding, sometimes inability to sleep because of pain in the recumbent position. Others complained of precordial pain—"angina" or "aortitis." Unlike Hanflig's patients (with later pathologic changes), these patients generally had no pain in the neck or definite limitation of neck motion, their commonest complaint was unilateral shoulder pain. Atrophy of small muscles of the hand was sometimes noted. Neurologic symptoms invariably coincided with the cervical region involved in the narrowed disk with or without hypertrophic arthritis. Oblique radiographic views (illustrated) showed actual narrowing of intervertebral foramina even when narrowed disks were present without hypertrophic arthritis.

Because of these experiences, Hanflig, and Turner and Oppenheimer rec-

ommended special clinical and radiographic examination of cervical spines in cases of unexplained shoulder and arm pains and of "angina" without evidence of cardiac disease. Although osteophytic changes are commonly seen on the anterior and lateral aspects of cervical vertebrae they are rarely found on the posterior aspect. Morton demonstrated the latter in three cases which showed that hypertrophic processes can develop posteriorly, and whether posterior or lateral, can extend into the spinal canal and press on the cord, or encroach on the cervical foramina and cause symptoms. Morton demonstrated the posterior projections clearly in oblique roentgenograms. Two of his three patients had pains in one or both arms, hand and neck. One had numbness and tingling of extremities, uncertainty in walking and girdle sensations accentuated by cervical hyperextension. A subarachnoid block was present. The projection was found at laminectomy, after which the patient was "considerably improved."

Treatment Treatment used in Hanflig's cases included a special type of stretching and manipulation. The patient was gently and carefully "hung" by his neck supported in a Sayre's sling suspension with block and tackle. Suspension was repeated for a few seconds each session and two or three sessions were given daily, usually only for a few days. At times, hot fomentations were given and a Thomas collar was worn between sessions. Results were often dramatic, severe pain disappearing immediately while the patient was suspended, returning thereafter but rather rapidly disappearing under continued treatment, usually within 10 to 21 days. Turner and Oppenheimer also noted marked relief with this method which was much easier than manual traction. Ultra short-wave therapy relieved a few, as did soft rubber soles and heels in mild cases. For usual cases of hypertrophic spondylitis short-wave therapy seemed valueless to Speeding. Gold was useless.¹⁸ Histamine ionization reputedly gave analgesia.⁹⁶

GOUT AND GOUTY ARTHRITIS

Gout was called a "forgotten disease."²⁶¹ Current statistics on its incidence foster contradictions that it is rare or that it is fairly common. Pringle found the incidence rising in some English and continental hospitals, falling in others. At the Philadelphia General Hospital a diagnosis of gout was made on only 47 of 414,296 patients admitted in 25 years (1905 to 1929), an average of less than two cases a year, but between 1929 and 1935 it was made on 30 of 146,992 patients.⁹¹ Cohen saw 40 cases the past 5 years. According to Schnitker, only 55 cases of "true gout" were admitted to the Peter Bent Brigham Hospital, Boston, between 1913 and 1935. Only five cases of gout were seen at the arthritis clinic of the Presbyterian Hospital, New York, in 1935, in the same period Herrick and Tyson saw six cases in private practice. Such statistics do not give an accurate index of the situation because the requirements of different physicians for a diagnosis of gout differ so materially. Hench stated that only one of

four or five cases of gout is correctly diagnosed in its early stages. But in some quarters, where physicians are loose with a diagnosis of gout, only one of two or three patients who receive such a diagnosis actually had the disease. In Hench's 100 cases of gout an average of 15 years had elapsed from the first attack of gouty arthritis to the first diagnosis of gout. "The necessity of taking 1500 years to diagnose 100 cases of classical gout does not indicate a proper understanding of this disease."

The features of classical gout were reviewed by several (Cohen, Hench, Herrick, and Tyson, Kersley, Pringle). In diagrammatic fashion, Hench described the basic pattern of gouty arthritis in relation to the appearing time of the four reported features of gout (podagra, hyperuricemia, tophi, punched-out areas in roentgenograms). He divided the course of gouty arthritis into two stages, each consisting of two phases. Stage I is that of acute, recurrent gouty arthritis with complete remissions (phase 1 is that of early attacks, phase 2 that of later, acute attacks with remissions and when hyperuricemia is more established and discoverable). Stage I lasts 3 to 42 (av 12) years. Stage II is that of chronic gouty arthritis (phase 3 is that of early chronic gouty arthritis with acute exacerbations but incomplete remissions, phase 4 the final, relatively symptomless, chronic gouty arthritis).

Discussing criteria for diagnosis of gout Hench noted 20 points expressed axiomatically

These were: Suspect gout when acute arthritis suddenly develops (1) after relatively trivial trauma, (2) after dietary excesses of holidays, birthdays, lodge-night, (3) after any surgical operation ("Acute postoperative arthritis is generally gouty"), (4) after the trauma, exposure and dietary insults of a fishing or hunting trip, (5) in spring or fall (gout has a definite seasonal incidence), (6) in the night between 2 and 7 a.m. (it may occur any hour, however), (7) in patients under certain coincidental treatments such as liver diet for pernicious anemia, ketogenic diet for bacilluria, salyrgan for dropsy, ergotamine tartrate (gynergen) for migraine, insulin for diabetes, (8) acute arthritis occurring in patients with polycythemia or leukemia is usually gouty, (9) to diagnose gout in females requires extra caution. 98 per cent of provable gout is in males, (10) gout is the commonest form of acute arthritis in men over 40 years, it may occur in youth, (11) suspect gout when acute arthritis comes on with dramatic speed, within a few minutes or hours, (12) when the pain is unusually severe, "the worst ever", (13) when the great toe is acutely, not chronically, involved, however, podagra may occur late or never in the disease. (14) when the maximal tenderness is at the mesial aspect rather than underneath or on top of the "bunion joint", (15) the appearance of an involved foot is suggestive (warm, bluish-red rather than cold and bluish-white as in atrophic arthritis), with edema and later desquamation of skin, (16) an acute arthritis of short duration (one to three) weeks and with full restitution of function should make one suspect gout, (17) any case with acute recurrent attacks of arthritis and complete remissions, possibly chronic arthritis later, should invite a diagnosis of gout, (18) since olecranon bursitis is several times commoner in gout than in any other disease, suspect gout in patients who have or give a (sought-for) history thereof, (19) suspect gout in patients with acute or chronic arthritis who have or have had chronic nephritis or renal colic (urate stones or gravel which incidentally cast no roentgenographic

shadow), (20) podagra is a common but not inevitable feature, hyperuricemia, 'characteristic' roentgenographic changes, and tophi are not early but rather late features of gout. Therefore in a case presenting a number of the features listed above one must not hesitate to entertain a diagnosis of gout in the absence of the four most characteristic features.

Some of these points were stressed by others also. Campbell noted the potency of trivial trauma as a provocative. Many stressed, but others minimized, the provocative nature of dietary excesses. One of Cohen's patients developed an attack after alveolectomy, another attack two days after appendectomy. Another patient noted an attack after tonsillectomy. Two of Herrick and Tyson's six patients were women who were taking liver extract orally, one for "a skin condition," the other for an unstated reason. Burchell reported a case of pernicious anemia with uric acid deposits in renal collecting tubules. No history of gouty arthritis was given, the patient suddenly died some time after stopping the use of liver extract in favor of ventriculin. Herrick and Tyson stressed the diagnostic importance of (1) the pattern of gouty arthritis, its recurrence with complete remissions, (2) a therapeutic test with colchicine. According to Graves (1863) gouty patients tend to grind their teeth and produce "bevelled teeth." "Graves' sign" was mentioned by Pringle, Finkle and Kersley, the last considered it by no means diagnostic and not always present. "Coates' sign," defined by Kersley as radial, by Pringle as ulnar, deviation of the terminal phalanx of the little finger, was mentioned. (One of us, P. S. H., has not noted Graves' or Coates' sign as a feature of gout in a study of several hundred cases of tophaceous and pretophaceous gout.—Ed.)

Clinical features of 84 cases were recorded by Cohen. There was a notable incidence among Philadelphia policemen and firemen. Eapen noted chronic advanced tophaceous gout in a Chinese male. Kendall, Fortner and Livingston noted a patient with a painful stump, the leg having been amputated for epithelioma. Later the stump became too painful for an artificial limb to be worn. From the stump a small nodule was excised, it contained scar tissue and giant cells. Within the cells, but not elsewhere, were "uric acid crystals." A diagnosis of gout was made thereon and also because the blood uric acid was 7.2 mg per 100 c.c. and the "usual medical treatment" for gout was followed by relief of symptoms.

(This case may have been one of gout. However, it is difficult for the reader to accept such a diagnosis without reservations. Crystals were identified only on their appearance, no murexide test was mentioned. There was no history of acute arthritis or other feature of gout. The presence of the crystals only within giant cells is an unusual feature, possibly due, as stated, to their destruction by the fixative used. The case is interesting and unique.—Ed.)

Of the 55 patients studied by Schmitzer and Richter, 17 (31 per cent) had clinical nephritis, of the vascular type in 15, and of the glomerular in two (one with nephrosis). Five died in uremia, four were examined post-mortem, three had vascular, one had glomerular, nephritis. Of the 38 pa-

tients without definite nephritis, 16 had albuminuria with little or no renal insufficiency. Compared to control groups, the incidence of hypertension in the 55 cases of gout was high (54 per cent), as was also that of vascular disease (67 per cent). According to Burchell, uric acid is occasionally deposited as free acid in renal tubules of the newborn (uric acid infarcts), or of leukemic adults, it is much more rarely deposited as urates, not free uric acid, in renal interstitial tissue in gout. Thus, interstitial deposition suggests gout, tubular deposition merely suggests hyperuricemia. In gout with leukemia, uric acid is deposited in tubules, urates in interstitial tissue. No renal deposits were mentioned by Schnitker and Richter.

(We understand that a formalin fixative was used. Many valuable specimens of kidneys and joints are spoiled for complete pathologic studies because of this error. Formalin-containing fixatives promptly dissolve urates. Galantha's (1935) method, using absolute alcohol as a fixative, is recommended—Ed.)

Atypical Gout Kersley accepted the following features of "atypical or covert gout": an articular history very similar to that of atrophic arthritis, supported by a familial history of gout, by Graves' or Coates' sign, perhaps by podagra, hyperuricemia, and radiographic alterations. It is "distinguished with difficulty from the type of rheumatoid arthritis occurring at the climacteric and from certain cases of focal arthritis." Pringle also suggested that perhaps many cases of climacteric arthritis, Heberden's nodes, fibrositis and panniculitis are atypical gout. (We cannot agree—Ed.) Manifestations of the latter, according to Cmunt, include dry eczema and hyperkeratosis of skin and nails, and pretibial edema ("due to irritation of periosteum") frequently seen in patients with hyperuricemia but no arthritis.

(We have seen many cases of tophaceous gout, always with the classical pattern of gouty arthritis, acute attacks, complete remissions, and we practically never have seen or heard of cases of atypical gout which went on to formation of demonstrable tophi. It is impossible for us, therefore, to accept a diagnosis of atypical gout in cases of arthritis chronic from onset—Ed.)

Wood presented four cases of "inflammatory disease in the eye due to gout." The patients had episcleritis periodica fugax. No gouty arthritis or other features of classical gout were present but the patients ate and drank to excess and in two of them the blood uric acid was "greatly increased" (4.6 and 4.1 mg) during the episcleritis and fell later (to 3.5 and 2.3 mg). In one case the disease responded to dietary restrictions. Tiny brown crystals "the size of average bacteria" were noted once in the cornea, and once in the posterior sclerotic. These were assumed to be urates, no chemical identification was possible as they were discovered in fixed specimens.

(The diagnosis of gouty episcleritis remains quite unproved. The illustrated "crystals" do not resemble urates. The therapeutic test was unconvincing. The pathologic reaction noted in the one specimen examined included none of the char-

acteristics of gout (giant cells, and so forth) of other tissues. We are very skeptical about the existence of atypical gout. To our knowledge tophi, the one infallible sign of gout, are practically always absent in such cases. In those very rare cases where tophi are present without arthritis (as yet), one still cannot blame every coincidental disease on gout. In a considerable experience with tophaceous gout we have not seen episcleritis or dermatitis as a feature—Ed.)

Laboratory Data It was generally agreed that hyperuricemia is usually, but not always, present in classical gout, and alone is of limited diagnostic value^{91, 251, 261, 303, 443}. The sedimentation rate is occasionally elevated^{87, 303}. Roentgenograms are generally negative in early cases and are of no help in diagnosis until late in the disease^{201, 261, 443}. Radiographic features in 12 cases were reported without clinical details⁵³⁵. Regardless of what joints may be affected, Scott and Kersley recommended roentgenograms of hands—they may show characteristic changes not seen elsewhere.

(In the experience of one of us, P. S. H., roentgenograms of feet show the characteristic signs earlier than those of hands. In the absence of other data a diagnosis of gout based on the presence of punched-out areas with chronic arthritis is usually erroneous—Ed.)

Pathology The articular pathology was briefly reviewed by Jordan.

Etiology and Pathogenesis Nothing new was presented. Cmunt approved the allergic theory and stated that certain purines seem harmless, but occasionally a purine-free diet, containing a food to which a patient is sensitive, may provoke gout. An 18 year old girl with a serum uric acid of 12 mg developed a "typical gouty attack" after eating a sour gherkin. The aromatic admixture of wine and not its alcoholic content may be harmful according to Cmunt. Uric acid acts as an allergen only in certain cases.

Tophaceous gout with extensive urate deposits on extremities and in joints was produced by Bollman and Schlotthauer in turkeys on a diet of turkey mash plus urea or raw horse flesh but not in those on turkey mash alone or with certain other additions.

Treatment His report on a "history of the treatment of gout" might as well have been titled a "demonstration of the slow progress of medicine," according to Schmitker. About the only things we don't do that the ancients did are "cupping, fancy poultices and pewking." It is particularly unfortunate that gout is so often unrecognized because, as Herrick and Tyson stated, of all the arthritides gouty arthritis can be most readily controlled. Cohen considered treatment highly successful "gout is controllable." The usual therapy was reviewed by several: for the attack, rest in bed, protection for joints, hot compresses, purgation, colchicum, cinchophen or salicylates and alkalies, a diet high in carbohydrates and nonpurine containing proteins, low in fats and free of purines^{91, 222, 261, 297, 303}. It is important to continue certain measures indefinitely after the attack is over. "Interval-treatment" includes purine restrictions, avoidance of alcohol and traumatizing activity, and the intermittent use of certain drugs.

During an attack Herrick and Tyson prescribed colchicine, 1 mg q i d the first day, t i d thereafter until symptoms subsided or diarrhea occurred. Cohen prescribed colchicine 1/120 grain t i d, Kersley used the tincture, 15 minims every three to six hours, with alkali and phenacetin or pyramidon. After the attack, Kersley prescribed cinchophen 75 grains t i d three consecutive days a week for three to four weeks, thereafter once a day three days a week, "with plenty of carbohydrates and calcium." Neocinchophen was used by Herrick and Tyson only for one week after an attack. Cohen's interval-treatment was a purine-low diet and colchicine 1/120 grain t i d one out of every four weeks.

(Cohen admitted that this did not lower the blood uric acid and it would appear that his patients so treated were usually "on the edge" of a gout attack. The pharmacologic effects of colchicine and cinchophen are quite different. Aside from the question of cinchophen toxicity there is no reason why both should not be used during an attack. There seems to be little rationale for continuing colchicine indefinitely, its value is chiefly analgesic, secondarily purgative. For those who are unable to control their gout by diet alone, the intermittent use of cinchophen seems more rational to some of us, but not to W. B., than that of colchicine, which does not affect urate excretion—Ed.)

Histamine injections were used by some, no results were stated.^{1 481} "There is probably no disorder so ill-adapted to the injudicious employment of physical methods as [acute] goutiness" (Ray). In intervals between attacks, spa therapy may be of value, however, it may initiate an attack if one is impending (Kersley).

Cinchophen Toxicity No case of cinchophen toxicity in gouty patients was reported. A patient with chronic polyarthritis (type not stated) developed nonfatal subacute yellow atrophy of the liver after taking oxyliodide 0.2 gm q i d for eight days.¹⁴³ Another patient⁴⁸³ had gonorrheal arthritis, he developed nonfatal agranulocytosis without jaundice or hepatitis after taking cinchophen 0.5 gm t i d for about three weeks. Palmer and Woodall reviewed all reported cases of cinchophen toxicity. In 141 (73 per cent) of the 191 cases cinchophen had been taken for "rheumatic diseases" ("arthritis" 70 cases, "rheumatism" 52, sciatica eight, gout six, lumbago four, rheumatic fever one). Of the 191 patients, 88 (46 per cent) died. The actual incidence of fatal and nonfatal cinchophen toxicity is probably much greater than reports would indicate. The vast majority of patients are able to take cinchophen over long periods without injury, but a peculiar susceptibility to it may cause disease or death from large or even small doses. Cinchophen had long been used by some without apparent harm, then jaundice and sudden death occurred. In some cases very small doses were used and withdrawn at the first sign of toxicity, yet death ensued. Palmer and Woodall concluded that there was no safe dosage or method of administration of cinchophen. They doubted the wisdom of its use even in gout which can often be handled "satisfactorily over a period of years without cinchophen." Comfort believed its use was justified in gout since there is no pharmacologic substitute for it in gout, but it should not be used otherwise. Its dangers can be reduced by discontinuing its use permanently not temporarily, at the first sign of toxicity and by strictly avoiding surgery.

procedures on those so affected, otherwise death may result Cinchophen being "the drug par excellence for gout" (and for certain other patients with arthritis or lumbago "who were living a miserable existence without it") Westfall considered the slight risk worth taking Of his miscellaneous patients 1589 each had taken from a few up to 4000 tablets (each tablet 0.5 gm) Between 25 and 100 tablets were taken by 886 patients, 250 to 500 tablets by 195, 500 to 1000 tablets by 47, 1000 to 1500 tablets by 11, more than this by 8 or 10, less than 25 tablets by the rest Several took the drug daily for three to four years Only one death occurred a woman with cholecystitis developed acute yellow atrophy Two others recovered from toxic jaundice, mild gastric symptoms were noted in 89 cases, a rash in eight, hives in five The great majority noted no symptoms whatever Westfall recommended that the full daily dose be given at one time, after supper, with a "teaspoonful of soda" It should never be given to a patient with liver damage, gastric distress or one on a restricted carbohydrate diet

In 1933 Barbour and Fisk produced liver damage in rats by large doses of cinchophen Recently Barbour, with Gilman was unable to repeat his previous work With large doses of cinchophen and tolysin they were unable to produce hepatic lesions in rats even after attempts to make the liver more susceptible to cinchophen by starvation diets to deplete liver glycogen or by large doses of fat or alcohol The growth of rats was unaffected by large doses of tolysin but was affected by cinchophen The antipyretic effect of tolysin appears early and is short, that of pyramidon is delayed but lasts longer A combination of the two produces a rapid, prolonged effect with no added toxicity

Unable to produce liver damage in rabbits or rats from cinchophen alone, Radwin and Lederer noted that cinchophen, in combination with intravenous injections of colon bacilli or streptococci, produced no hepatic lesion not produced by infection alone Sensitivity of patients to cinchophen is therefore a peculiar one not apparently related to previous or coincident hepatic infection Peptic ulcers and gastric hypersecretion, but no hepatic or other lesions were produced in dogs given cinchophen by Stalker, Bollman and Mann Reid and Ivy also produced gastroduodenal ulcers but no hepatitis in 100 per cent of 15 dogs The administration of gastric mucin markedly prevented such lesions and acute toxicity in 82 per cent of 13 dogs

Hench (1933 et seq) and others reported that jaundice from cinchophen, and other types of jaundice, produced a marked reduction in symptoms of patients with atrophic arthritis or primary fibrositis In Diack's case of polyarthritis with hepatitis and jaundice from oxyiodide the condition of joints during jaundice was not described, it was noted that five months later "arthritic pains still persist to a slight degree" The phenomenon described by Hench is apparently relatively specific for atrophic arthritis and primary fibrositis Others have described certain types of arthralgia or arthritis coming on after, or even with, hepatitis and jaundice Sager saw a young

woman with "grippe" followed by febrile polyarthralgia (no swelling). About two months later, without the use of cinchophen, jaundice developed, icterus index 100 bilirubin 7 mg per cent. "With the deepening of the jaundice the severity of the arthralgias had diminished although they never disappeared entirely." Of 208 patients with parenchymatous liver degeneration seen at the Mount Sinai Hospital since 1929, Sager found that 30 (14 per cent) had had "arthritis" or severe arthralgia, of whom 10 had had cinchophen but 20 had not. Cinchophen has been used with great caution since 1932 but Sager's statistics showed that the frequency of arthritis and jaundice did not decrease after 1932. He concluded that certain patients with "arthritis" will develop catarrhal jaundice whether they take cinchophen or not and cinchophen is too often incorrectly blamed for this jaundice.

(In view of the phenomenon noted by Hench and current attempts to reproduce it therapeutically in atrophic arthritis, a more detailed review of these cases by Sager would be of considerable interest. Sager made no attempt to classify arthritis or arthralgias and did not give any time or symptomatic relationships between jaundice and joint disease. Sager called his case of febrile polyarthralgia without swelling "infectious arthritis", it was probably not atrophic arthritis—Ed.)

Uric Acid Problem Studying uric acid clearance tests on two nongouty patients McLester concluded that the renal excretion of uric acid is of the same type as that of urea rather than of the type of creatinine and the non-metabolized sugars. Larson and Chaikoff (1935) showed that injections of insulin or of epinephrine increase the blood and urinary uric acid in Dalmation dogs, the urinary allantoin in other dogs. Larson and Brewer have now shown that insulin affects purine metabolism, not per se but indirectly through epinephrine, insulin hypoglycemia produces an increased secretion of epinephrine from the adrenals.

PSORIATIC ARTHRITIS ARTHROPATHICA PSORIATICA

Psoriasis is common and is frequently seen in patients with all manner of articular complaints. Under the term "psoriatic arthritis," writers have listed cases of psoriasis with rheumatic fever, with atrophic arthritis or with hypertrophic arthritis. The reaction to such an indiscriminate application of the term to such cases, the great majority of which have merely been of psoriasis occurring coincidentally with unrelated joint disease, has been that most rheumatologists refuse to believe there is such an entity. A current example of loose usage follows: "Occasionally in the aged, pain and swelling in the larger joints accompany the [psoriatic] rash. This is the so-called psoriasis arthropathica"¹⁵² Others have used certain clinical and roentgenologic criteria to restrict the term to a special syndrome. The matter was discussed by Shlonsky and Blake, who reported a case of what they believed to be true psoriatic arthritis.

A female aged 57 years had suffered with progressive psoriasis and polyarthritis, both of which began 20 years before. Psoriasis was generalized with coalescent

lesions, nails were thickened, crusted, grooved. Multiple joints, especially those of distal extremities, were involved in a destructive process, with ankylosis in a few joints but with massive bone absorption and the development of "opera glass fingers and toes" ("main en lorgnette") from a veritable dissolution and telescoping of certain joints of wrists, fingers and toes. The patient's serum contained no agglutinins for hemolytic streptococci. The objective and radiographic appearance of the joints was described in detail. Besides osteoporosis and destructive changes, the radiographic feature was a tapered narrowing of articular ends of bones with the production of "ball and socket joints."

(One of us, P S H, has called these "pencil-to-pencil joints" or "pencil-in-cup joints" because the end of one bone is destroyed to resemble not a ball but a dull pencil which may oppose a similarly destroyed bone-end or one presenting the shape of a cup—Ed.)

Shlonsky and Blake considered it a most extensive case of psoriatic arthritis, simulated by only one reported case (Bauer and Vogl, 1931). They believed that the psoriasis and arthritis were etiologically related but were uncertain whether this type of arthritis is peculiar to psoriasis.

(We are divided in our opinion on the specificity of this entity. Some of us (W B, F H) believe that psoriatic arthritis is merely atrophic arthritis and associated psoriasis, this being such a case, and that similar extensive destruction of joints may occur without psoriasis in cases of atrophic arthritis. Others of us (P S H, C H S) regard psoriatic arthritis as an entity, a disease which objectively affects central and less peripheral joints, much as in atrophic arthritis, but which has certain pathognomonic features, chief of which is the proclivity with which it affects the distal joints of fingers and toes in a destructive arthritis in conjunction with psoriasis of nails²⁴⁷. Although psoriatic arthritis is often fairly mild, it may be severe. Hench has seen in severe cases only, the peculiar type of bone destruction and dissolution noted in this case, an appearance which he has never seen exactly duplicated, even in the most severe cases of atrophic arthritis—Ed.)

Ingram noted the "association of rheumatic manifestations [of unstated type] in muscles, nerves and joints" in three of twelve cases of pustular plus "ordinary" psoriasis, but in none of 20 cases of pustular psoriasis without ordinary psoriasis. According to Duckworth, nails are not usually affected in cases of pustular psoriasis.

(In scaly, disseminated or patchy psoriasis, nails are commonly involved and sometimes with them the terminal phalangeal joints—Ed.)

Treatment Most reports on the treatment of psoriasis did not mention joint lesions. Some believe that psoriatic arthritis in its early stages can be largely controlled by vigorous therapy to control the psoriasis. If this is true, treatment of the skin is an important feature of the therapy of psoriatic arthritis. In line with the beneficial effect of summer sunshine on psoriasis, striking improvement in three cases of "notoriously stubborn psoriasis" was noted by Krafka from the use of "massive" (20,000 units daily), later "maintenance" (4000 units daily) doses of vitamin D (haliver oil with viosterol). Small doses were useless. The largest dose was first given in 10 day courses with 10 day rest periods. When the psoriasis had

cleared, the smaller doses were used. Thurmon noted "a decided beneficial effect" from the use of a noncolloidal organic sulfur solution in 70 cases of psoriasis. Colloidal manganese was recommended by Spitz, "psorimangan" by Schwartz. The histopathology of the skin lesions was described,³⁴ and a historical review of psoriasis was published.³² Joints were not mentioned in the five papers last mentioned.

HEMOPHILIC ARTHRITIS

Of 98 patients with hemophilia seen by Thomas, 79 per cent (77 cases) had hemophilic arthritis, 61 per cent (60 cases) had permanent joint deformity. Joints most commonly affected were knees (68 per cent), ankle (56 per cent), elbow (53 per cent), hip (16 per cent), fingers (15 per cent), wrist (5 per cent), spine (3 per cent), toes (2 per cent). Shoulders generally escaped involvement. One case of spinal involvement had been misdiagnosed Pott's disease. One patient had a Volkmann's contracture after extensive hemorrhages in an arm. The patients' ages ranged from the newborn to 65 years. Additional cases of hemophilic arthritis were reported 11 by Timperley, Naish and Clark, one by Sutton. Firor and Woodhall saw an unusual case of a large, hemophilic, pseudotumor of a thumb with destruction of both phalanges and metacarpals. Previously diagnosed bone sarcoma, the unique lesion represented the end stage of traumatic hemophilic hemarthrosis. "The march of events in small bones has never been ascertained roentgenographically." The pathologic results were similar to those which occur in large bones or joints, but instead of regression and eventual ankylosis, progressive destruction and cutaneous rupture may also occur in small bones and joints.

Crandall found reported four doubtful but no certain cases of hemophilia in negroes. Crandall cited "apparently the first instance" of hemophilia and arthritis in a full-blooded negro. Only five cases of Volkmann's contracture in hemophiliacs have been reported, two new cases were seen.^{263, 542}

Roentgenographic and pathologic features²⁴⁵⁻²⁴⁷ of hemophilic arthritis were briefly reviewed.¹⁷⁶

Treatment For joints. This was reviewed by Thomas. Injury to joints must be avoided. Affected joints must be put at rest. In the acute stage, ice bags may lessen pain, reduce swelling, and shorten invalidism. Adequate arterial pressure distal to large hematomas must be insured by blood transfusions if necessary. When contractures have occurred, treatment consists of very slow traction, careful diathermy, gentle massage, carefully applied casts and turnbuckles followed by slow, cautious motion. This may require months during which joints are rested in bed, later, casts, crutches and canes. Firor and Woodhall amputated the thumb affected by the hemophilic pseudotumor safely and rapidly by electrocautery. Normal healing resulted, a remarkable and rather prolonged postoperative reduction

of clotting time from five hours to five minutes occurred, perhaps from some mobilization of thromboplastic substance incident to cauterization

For the hemophilia Having used various ovarian substances, corpus luteum, whole ovary, and so forth, with little effect, De Silva controlled hemorrhages of hemophiliacs and others with theelin

(Data on the cases reported were too meager for one to accept the diagnosis of hemophilia or to approve the conclusion—Ed)

A placental extract markedly reduced the clotting time in 11 of 15 cases seen by Eley and associates. Oral use was more effective than intramuscular use. Timperley, Naish and Clark had "excellent results" from a new mixture of potassium bromide and egg white given intramuscularly or intravenously. It did not produce local or general intravascular clotting but reduced the clotting time of blood and controlled hemorrhage of 13 patients so effectively that they endured with impunity such unusual trauma as pounding with a hammer, jumping from chairs, kicking a football, running over uneven ground, dental extraction, and so on. In testing the method "patients were encouraged not to spare themselves the knocks and cuts which of habit they had avoided." Russell's viper venom, applied locally, controlled dental hemorrhages.^{20 73} In Sutton's case of hemophilic arthritis and epistaxis, the venom used locally and orally was ineffective. Injections of whole parental blood and coagulin were helpful.

Of interest was a study of blood coagulation in hemophilia by Patch and Stetson. (In evaluating therapy it should be remembered that the clotting time of hemophiliacs may vary markedly from day to day or from week to week—Ed)

ALLERGIC, METABOLIC AND ENDOCRINE ARTHRITIS

Though still used by some, these terms are being employed with more caution, they have not yet been accurately defined. Some use the terms to indicate an arthritis presumably different from any other, others consider them more or less synonymous with either atrophic or hypertrophic arthritis. Thus, Pringle wrote, "Though there is not sufficient laboratory or clinical evidence to show that rheumatoid arthritis is a definite disease due to errors in metabolism, clinically I believe that the primary form is metabolic and probably due to some imbalance in the endocrines." Nissen believes that "psychogenic (endocrinal and metabolic) factors" underlie many obscure cases of arthritis. Wootton expressed the belief that arthritis represents food allergy or bacterial allergy in the presence of hyperparathyroidism. "Practically all non-septic joint disturbances begin as an allergic reaction" to bacterial allergens in early life, to food allergens later. But bone changes will not take place unless there is a concomitant hyperparathyroidism.

(This is pure speculation, no proof of any sort was offered—Ed)

Allergic Arthritis The application of the allergic hypothesis to rheumatic fever, atrophic arthritis and gout has been noted. No one has been

able to set up any one articular syndrome as "allergic arthritis" or to prove that any of the arthritides are chiefly or solely the result of bacterial or food allergy. Young noted that patients with atrophic arthritis are susceptible to skin allergy but not especially to hay fever or asthma. But patients with such allergy rarely had arthritis. He believed that atrophic arthritis might represent a bacterial allergy but concluded from skin and diet tests that food allergy played no role. Some rheumatism specialists consider intermittent hydrops the nearest approach (aside from serum sickness) to an "allergic arthritis." Supporting this view, Lewin and Taub presented a case of "allergic synovitis due to ingestion of English walnuts."

A boy, aged 16, had intermittent (every two to three months) stiffness and swelling of knees for 10 years, attacks lasting 24 hours. His parents had hay fever, and urticaria from strawberries and tomatoes, he did not. A typical attack in knees was induced within 72 hours of eating the meats of half a pound of English walnuts. Skin tests were positive to English walnuts only. Subsequent provocative and therapeutic tests were positive.

"Metabolic Arthritis" Aside from applying this term obliquely to atrophic or hypertrophic arthritis and more directly to gout, current writers failed to stress, or clarify it further.

Endocrine Arthritis The idea that endocrine disturbances may act as predisposing or aggravating factors in atrophic or hypertrophic arthritis is admitted by many rheumatologists and emphasized by a few. But this is a different matter from saying that a certain type of arthritis is due solely to the overfunction or underfunctioning of one particular endocrine gland, in which case a true endocrine arthritis would exist (and not, for example, an infectious arthritis modified by endocrine factors). Ellman and O'Brien accepted a relationship between hypertrophic arthritis and "endocrine imbalance," presumably an ovarian deficiency with or without hypothyroidism or frank myxedema. "A lowered basal metabolism occurs in a noticeably large number of these patients."

(But for hypertrophic arthritis to be a true endocrine arthritis due to hypothyroidism, a lowered rate must *always* be present, which it certainly is not—Ed.)

Finkle argued that arthritis may sometimes occur with myxedema. Others (Schmitker et al.) have noted "chronic arthritis" occasionally in cases of spontaneous myxedema, and muscular pains in patients with induced myxedema (post-thyroidectomy).

(According to Monroe, 1935, myxedematous patients rarely have atrophic, often have hypertrophic, arthritis. The percentage relationship was too low to justify regarding myxedema a primary factor—Ed.)

Peers, studying metabolic rates in various arthritides concluded that "the true arthritic is a nonmyxedematous individual." The low metabolic rates seen fairly often in arthritic patients "are not due to a lack of thyroid hormone but are brought about in some other fashion." Tidy

also concluded that neither hypothyroidism nor hyperthyroidism is the primary cause of any chronic rheumatism, even though thyroid extract may help arthritics with low rates, "there is no reason to ascribe any specific action to thyroid"

"Climacteric Arthritis" This holds a precarious position in the family of arthritides. It is placed in the classification of the Ligue Internationale Contre la Rheumatisme as synonymous with "endocrine, metabolic, hypoglandular rheumatism, villous arthritis, rheumatic gout, gout in women". The classification of the British Medical Association includes "chronic villous arthritis, mainly occurring in women at or about the climacteric". Neither climacteric nor villous arthritis is recognized by the classification of the British Ministry of Health, nor in the official nomenclature of the Royal College of Physicians. Recently a subcommittee of the Royal College of Physicians listed "climacteric arthritis (villous type)" twice, deciding that it may produce either a "rheumatoid type" or an "osteo-arthritic type" of chronic arthritis¹⁷. Thus, three views are held that "climacteric or villous arthritis" does not exist (this view is held by most of us—Ed), that it is an entity with special clinical and pathologic features, or that it is an entity which produces now one, now another pathologic reaction.

Etiology of Climacteric Arthritis Seven writers currently expressed their views thereon. Although the majority believed that climacteric arthritis was due to some kind of endocrine deficiency, they were not certain just what kind. The cause is probably hypothyroidism according to Thomson, who nevertheless prescribed pituitary extract also in some cases. A Court noted the disease in florid stout patients "with signs of thyroid deficiency". Gordon considered it "an endocrine deficiency especially of thyroids". Fox did not incriminate endocrines but considered it due to "disturbances of digestion, metabolism and excretion," to "toxic or metabolic factors" due perhaps to "the formation of abnormal substances or to simple failure of excretion".

(Obviously the above writers were very hazy as to the cause. None gave laboratory data indicating a consistent deficiency of ovarian or thyroid function. It should not be difficult for those who believe in the entity to apply to reputed cases the newer laboratory methods for estimating ovarian and other deficiencies. This would do much to settle the argument—Ed.)

Clinical Aspects of Climacteric Arthritis There was no uniformity in the clinical picture presumably characteristic of "climacteric arthritis". Some regarded it as synovitis, others as arthritis. According to Thomson it "occurs exclusively in middle-aged women, affects the knees and occasionally one or more other joints, such as wrists". It affects knees according to Buckley, knees but also first metacarpal joints according to Gordon. A Court considered it "a gradual increasing stiffness and pain in affected joints, usually the knees". Fox separated "climacteric arthritis" or the "arthritis of middle life" from both atrophic and hypertrophic arthritis.

He regarded it as "different from the much more serious rheumatoid arthritis of the young, on account of its mode of onset and the order in which the joints are affected, its more favorable course, its limitation often to a few joints, and its occurrence in comparatively healthy people" According to him, intermissions of one or two years are not uncommon, after a few years there is comparative quiescence with localization in one or two or a few joints, a "less profound constitutional disturbance, and thus a more favorable prognosis" Incidentally, I have noticed in many cases that the arthritis has been almost or quite confined to the left side of the body" It affects married women, especially those with children, much oftener than the single The average age of onset in Fox's cases was 48 (range, 37 to 54) years

Hall's conception of "menopausal arthritis" was much more inclusive He studied 49 women who developed joint distress coincident with the onset of menopausal symptoms Of the 49 cases, 23 were "castrates" (two by roentgen-ray, 12 by operation, nine by unilateral oophorectomy with subsequent "stormy menopause"), 26 experienced a physiologic menopause Of the castrates, six developed atrophic, four hypertrophic arthritis, 13 "arthralgia" Of the others, 12 developed atrophic, five hypertrophic arthritis, nine arthralgia Thus menopausal arthritis simulated atrophic arthritis in 18 cases, hypertrophic arthritis in nine cases, "arthralgia" in 22 cases Unable to determine concentrations of urinary estrin or prolan A, Hall based his diagnosis of menopausal arthritis on the coincident appearance of menopausal and articular symptoms, but especially on the beneficial effect of estrogenic substances on the former Joints involved, in order of frequency, were hands, knees, neck, wrist, fingers, ankles and lower back In marked cases 25 to 50 per cent of all joints were involved "Arthralgia" consisted of absence of swelling or of marked tenderness, heat, redness, crepitus or altered function, presence of irregular pain, morning stiffness, slight puffiness and tenderness, pains coming and going abruptly, often appearing markedly at night, perhaps due to vascular spasm

Pathology of Climacteric Arthritis According to Thomson and a Court "proliferative synovitis" is primarily present, with fine crepitations audible and palpable on joint motion Fox and Gordon considered it different from, but often ending in, osteo-arthritis "The typical change in the knee joint is a villous overgrowth of the synovial membrane, passing in a few years into a later stage of degenerative osteo-arthritis" Hall's views were noted To Fletcher the pathologic reaction "may be rheumatoid in type, more usually it is villous or osteo-arthritic"

Roentgenographic Changes of Climacteric Arthritis These were not specifically defined Scott found no radiologic picture characteristic of "climacteric arthritis"

(We are divided in our views Most of us do not recognize it as an entity, believing that it is a mild senescent hypertrophic (degenerative) arthritis with or

without its commonly associated fibrositis, or that it is atrophic arthritis in a patient at the menopause. Its supposed pathology of primary and dominant synovitis, later associated with degenerative changes, presents a hybrid between that of atrophic and hypertrophic arthritis, or else represents a mixture of the two, the synovitis of mild atrophic arthritis coincidentally or subsequently associated with the inevitable degenerative changes of hypertrophic arthritis. Matters could be distinctly clarified if the protagonists of the entity would present pathologic data on "typical cases." Do they present synovial pannus formation, lymphocytic collections characteristic of atrophic arthritis, and the cartilage changes of atrophic arthritis, do they demonstrate the usual picture of hypertrophic arthritis, or do they present a specific and unusual type of synovial and cartilage involvement?—Ed.)

Treatment of Climacteric Arthritis Usual treatment was thyroid extract, weight reduction, correction of posture and flat feet^{118, 181, 546}. Iodine and pituitary extract were recommended⁵⁴⁶. Fox, believing it a metabolic, not an endocrine, disturbance, did not recommend endocrines but general measures to promote elimination and reduce strain. The osteo-arthritic stage can be prevented, according to Gordon. "If properly treated by increasing the local synovial activity, by heat, and other means, and by redressing the endocrine deficiency, especially that of the thyroid, the original arthritic process can be cured before any osteo-arthritis has supervened." Without details Fletcher recommended estrogenic therapy.

Intramuscular injections of theelin or progynon controlled menopausal symptoms in all of Hall's 49 cases. From 50 to 100 per cent of relief in joints was noted in 91 per cent of the 22 cases of arthralgia, 66 per cent of the 18 with atrophic and 44 per cent of the nine with hypertrophic arthritis. Treatment and results differed in the castrates and those with a physiologic menopause. Individual doses varied from 200 to 2000 rat units (1000 to 10,000 International units). Some received 6000 rat units weekly. Relief (50 to 100 per cent) of joints was experienced by 82 per cent of the castrates, by 65 per cent of the others. The former required more than 2000 rat units in oil per week, noncastrates required 2000 rat units or less weekly. Usually at least six doses were necessary, doses being given at five to seven day intervals.

Acromegalic Arthropathia Human "acromegalic arthritis" has been noted (for example, Erdheim, 1931). Silberberg produced its pathologic counterpart in guinea-pigs by injecting an acid extract of cattle anterior pituitary gland. First noted were hypertrophy and hyperplasia of cartilage cells, first in the transitional, later in the sliding and pressure zone. This proliferative process was then followed by liquefaction and degeneration of the growing cartilage, with ulceration of its surface. Calcification of cartilage was later noted. Since similar or greater changes were produced in thyroidectomized guinea-pigs, the pituitary extract obviously acts without intermediation of thyroid.

Arthritis and Parathyroids The arguments of those few physicians who "without good evidence" attempted to relate arthritis to hyperparathyroidism have been about silenced. Wootton argued relationship, not di-

rect but indirect, between various articular diseases and parathyroids. His "commonplace viewpoint" is very hypothetical and fanciful, with absolutely no scientific proof to support it. Reviewing past arguments favoring a relationship, Jessop, Wilder and Howell, Parsons and others agreed that none of the arthritides have any proved connection with hyperparathyroidism. Apparently considering the argument "closed" or fruitless, most current writers on hyperparathyroidism did not even mention joints.

Although the skeletal pathology in clinical hyperparathyroidism is osseous, not articular, it behooves rheumatologists to be familiar with hyperparathyroidism because of its frequent "rheumatic-like" symptoms. The disease characteristically produces skeletal aches and pains particularly in the back (72 per cent).⁷³ The osteoporotic form of the disease (the early stage of the classic type without cysts or bone tumors, when symptoms are produced by generalized decalcification) is often diagnosed "rheumatism." One should suspect hyperparathyroidism in patients with generalized "rheumatic" or "neuritic pains" or with unexplained arthritic pains of the nerve root type,^{53, 333} but *only* if they (repeatedly) exhibit the classical chemical features. In hyperparathyroidism blood calcium and phosphatase and urinary calcium and phosphorus are high, blood phosphorus is low. In chronic atrophic and hypertrophic arthritis the blood and urine calcium and phosphorus are generally normal and blood phosphatase is normal or slightly low.

Several of the recent cases of proved hyperparathyroidism presented "rheumatic" symptoms.

One patient's chief complaint was pain in feet, legs and back, seemingly affected by weather, and the condition was treated as "rheumatism" for six months.⁶⁸ Another had weakness and severe pains in arms, lumbar region and legs called "sacro-iliac strain and sciatica."¹⁷ The aches and pains of one had been called "arthritis", another had pain and tenderness of a sacro-iliac joint, limited motion of spine and a tender hip.⁸⁶ One case of severe pain in neck, back, and both legs was labelled "neuritis" for eight years.²³³

Others noted pains in back and shoulders on motion,^{283, 436} but specifically stated that the pains were not in joints. In three cases of Merritt and Lattman, articular complaints were noted: one patient had a painful swollen knee with cystic bone destruction at the distal end of the femur; another had a painful shoulder, hip and back; the third had painful, tender hands, forearms and shoulders called "chronic arthritis" by a leading rheumatologist.

(We cannot be sure that these three cases were of hyperparathyroidism. Chemical studies were incomplete or not done, biopsy was not made, the patients were treated by roentgenotherapy.—Ed.)

Injectations of parathormone in rats produced osseous and other lesions characteristic of clinical hyperparathyroidism but no articular lesions (Johnson, 1932). Animals fed large doses of vitamin D will also develop similar osseous changes and metastatic calcification. In addition to these, however, Fang and Miltner noted degeneration and calcification in articular cartilage and intervertebral disks (lesions not noted in clinical hyperparathyroidism). The lesions disappeared after administration of vitamin D was stopped.

For those interested in the general subject, its clinical types, chemical and radiologic differentiation, urologic features, complications and treatment, several other excellent reports are available, in particular, Wilder and Howell's summary of 135 reported "proved cases" ^{42, 71, 201, 212, 268, 304, 378, 386, 411, 412, 426, 456}

Chemical "Arthritis" or Arthralgia Arthritic patients receiving thyroid extract sometimes note increased joint symptoms, presumably due to heightened sensitivity and lowered threshold for pain. However, nonarthritic patients with myxedema, or with low basal rates without myxedema, commonly develop generalized arthralgia and particularly myalgia (influenza-like) for a few days shortly after starting thyroid therapy (Plummer and Boothby, 1927). One of the toxic manifestations of excess alkali therapy for duodenal ulcer is aching pain ("grippe-like") in muscles and joints (Hardt and Rivers, 1923). Such forms of toxic myalgia and arthralgia might be designated myalgia or arthralgia medicamentosa. Genner has used the term "paratherapeutic articular disturbance" to indicate articular symptoms from antisyphilitic treatment. Of 2235 patients under such therapy, 79 (3.5 per cent) developed articular disturbances, usually polyarticular, generally only arthralgia, occasionally with slight swelling and redness. Symptoms sometimes lasted months after therapy was stopped. In two cases severe arthralgia necessitated hospitalization. Bismuth, not arsphenamine, was held generally responsible. Of patients with arthralgia, 42 per cent were receiving bismuth alone, 54 per cent arsphenamine and bismuth, and only 4 per cent arsphenamine alone. Common signs of bismuth intoxication were jaundice (116 cases) and erythema (148 cases). Although jaundice and arthralgia usually did not occur together, the combination was noted in 10 cases, jaundice appearing before the pain in three, after the pain in seven cases.

(No note was made on intensity of jaundice or any ameliorating effect of this type of jaundice on joint pain—Ed.)

Wolf (1925) believed the arthralgia was caused not by a direct toxic effect of the medicine on joints but by an indirect effect through impairment of hepatic function, so that noxious autolytic products enter the blood stream and produce, among other effects, articular pain. Genner favored a "direct toxic-medicamental effect" in spite of the frequency of hepatic symptoms. "The individual tolerance is dependent on the detoxicating power of the organism (largely dependent on hepatic function) and on the functional capacity of excretory organs. When these safety valves fail to work properly, toxic by-effects appear."

MISCELLANEOUS TYPES OF JOINT DISEASE

Synovitis, Transitory Synovitis of Hip Joints Children under eight years of age are affected. Finder saw 22 cases subsequent to 1916. Symptoms were a limp, pain frequently referred to knees, night cries, restlessness,

often slight fever and leukocytosis. Since synovia alone was involved, roentgenograms were negative. Presumed causes were trauma and infection. Treatment included rest, traction, sometimes immobilization, physical therapy. "The outcome is uniformly good."

(May these not be cases of atypical atrophic arthritis?—Ed.)

Tenosynovitis Spencer reviewed features of the traumatic, suppurative, gonorrheal, syphilitic, tuberculous, and "rheumatic" types. Early and adequate incision is necessary in synovial whitlow (suppurative tenosynovitis).⁴⁶⁰ Cohen's patient with "tenosynovitis crepitans" of a wrist, precipitated by trauma, unrelieved by rest and physical therapy, had oxaluria and had had an oxalate renal stone. Measures to stop oxaluria (special diet and medicines) relieved wrist pain within three weeks. Six other patients responded similarly. Patients refused biopsy. Cohen recommended metabolic studies and this treatment in similar cases.

Stenosing Tendovaginitis DeQuervain's Disease Occupational trauma produces "snapping thumb or finger" caused by a localized thickening of the tendon as it passes with effort through a partially stenosed tendon sheath. Tendons themselves are usually normal. Although not uncommon, only 200 cases have been reported. Thirty-five new cases were noted (Burns and Ellis, Patterson, Zelle and Schnepf). A thumb is usually affected, with slight swelling and marked tenderness over the radial styloid. Voluntary abduction or forcible adduction of the thumb is painful. Conservative treatment is generally unsuccessful. "Immediate relief" is obtained by simple incision of the constricting sheath.

Intermittent Hydrarthrosis It is uncertain whether this is a pathologic, or a peculiar physiologic, reaction of the articular lining or of those elements which produce synovial fluid. Pathologic reactions in one case were slight thickening of the lining layer of cells without increased fibrosis or perivascular thickening (Ghormley and Deacon). In Collin's case the total synovial cell count was 1600 per cu. mm. in one knee, 2500 in the other with 58 and 71 per cent polymorphonuclears.

Synoviomas Black described a benign synovioma arising from a tendon sheath or bursa of a hand following injury. Its cells produced a mucinous fluid resembling synovial fluid. Early symptoms of malignant synoviomas may resemble those of "arthritis." Synovial sarcomas are rare. Knox reported 19 cases from the literature and three new ones. Knee joints were affected nine times. First symptoms were swelling, tenderness and pain, usually before, occasionally after, the appearance of a mass. They rarely arose in arthritic joints. Malignant tumors of joints, bursae or tendons are fibrosarcomas or synovial sarcomas. The latter are resistant to radiation, not cured by amputation.

Chondromas These were classified by Moore as (1) simple ecchondroma, enchondroma, (2) compound osteo-, fibro-, myo-, angio-, papillary-chondroma, (3) malignant chondrosarcoma. Simple or malignant second-

ary changes may develop, in order of frequency calcification, ossification, fatty degeneration, mucoid softening, cystic degeneration, surface ulceration, sarcomatous degeneration, chondroma-sarcoma Baker discussed osteochondromas, the commoner type A case of chondroma of the head of the fibula, described by Moore, was regarded most unusual because "few parts of the skeleton are so seldom the site of pathologic affections and anomalies as the proximal end of the fibula" Multiple loose bodies in joints most often arise from synovial osteochondromatosis, a metamorphosis of synovial membrane into a benign tumor^{194, 195}

Hypertrophic Pulmonary-Osteo-Arthropathy A case with usual features was seen by Kline, the patient was a boy with pulmonary tuberculosis

Arthritis and Scleroderma A child developed cicatrizing morphea (circumscribed scleroderma) over buttocks, legs, abdomen A few months later pain and tenderness involved knees, hips and ankles without swelling or inflammation Ankylosis of hips, flexion of knees, stiffness of feet, bone atrophy and calcium deposits in patellar ligaments and Achilles' tendon ensued (Crawford)

Supratrochanteric Calcification Calcified deposits near the greater trochanter may cause pain and disability of a hip Such deposits were found by Goldenberg and Levinthal in none of 100 patients under 15 years of age, in 30 (5.4 per cent) of 550 patients over 15 years, 20 affected the gluteus medius tendon, eight the bursa between the tendon of the gluteus medius and the greater trochanter, two the under surface of the gluteus medius Reflex spasm of the latter limited abduction and internal rotation of the hip The condition is analogous to that affecting the supraspinatus muscle in "sub-acromial bursitis" Surgical removal of deposits provides a cure

Miscellaneous Conditions Conditions which give rise to symptoms which imitate arthritis were discussed by Kerr syphilitic dactylitis, bursitis, myositis or periostitis, scurvy, beriberi, rickets, Raynaud's disease, leprosy, cervical rib and the *scalenus anticus* syndrome, erythralgia, peripheral neuritis

(One might add lupus erythematosus, periarteritis nodosa, and others—Ed)

Early symptoms of spinal metastatic carcinoma from the prostate are often considered arthritic In Duncan's 85 cases with secondary growths in pelvis and spine, pain was usually worse at night, better when patients got up and walked Spinal motion was freer than in arthritic patients Rosh noted cases of Hodgkin's disease with vertebral involvement

DISEASES OF MUSCLES, AND FIBROUS TISSUE, FIBROSITIS

Fibrositis denotes swelling and proliferation of white fibrous tissue anywhere in the body in response to injury and various toxic influences, with the secondary effect of pressure on arterioles and nerve filaments⁴⁷⁵ It is no more one disease than is arthritis On the basis of supposed cause,

Slocumb noted these etiologic types (1) primary fibrositis—unaccompanied by and independent of, any other definite disease, (2) secondary fibrositis—that secondary to some known cause or primary dominant condition such as trauma, gonorrhea, rheumatic fever, gout, hypertrophic or atrophic arthritis. This groping for order indicates a present knowledge of fibrositis inferior even to that of arthritis. Probably half the symptoms of hypertrophic arthritis are due to associated "senile fibrositis" according to Hunt and Gordon who believe it is due not to foci of infection but to a metabolic fault from impaired circulation and faulty elimination. Treatment of fibrositic nodules, so common with atrophic arthritis, will give some relief (Wilson). The gouty nature of some forms of fibrositis and lumbago was suspected.^{1,1 360}

Primary Fibrositis This condition, of unknown cause and independent appearance is the most common type, "the commonest form of acute or chronic rheumatism" (Scott Slocumb). Almost everyone suffers with one of its forms at least once in his life. Telling called it perhaps the commonest cause of persistent and recurring pain. Copeman and Slocumb noted the two stages of the lesion: the early acute stage of effusion—a mild or severe localized inflammatory (serofibrinous, not cellular) exudate perhaps seen as a puffy swelling, the later stage of organization, with the production of fibrous thickening, nodules and cords.

The anatomic types were listed^{102 49}: (1) intramuscular ("muscular rheumatism," "myositis," "myofascitis"), (2) periarticular (capsular) fibrositis ("capsulitis," "capsular rheumatism"), (3) bursal fibrositis, "bursitis" (4) tendinous fibrositis, for example, palmar or Dupuytren's fibrositis, (5) panniculitis, fibrositis of subcutaneous tissue, (6) perineural fibrositis, "interstitial neuritis," for example some forms of sciatica and brachial neuralgia.

Symptomatology This was reviewed by Slocumb and Copeman. Considering differences in situation of the disease it is obvious why symptoms are so protean. The common characteristic symptoms of the various anatomic types were aching, stiffness and soreness—particularly when the part is put on a stretch, little or no objective changes except the palpable indurations, much fatigue, chilliness and general hypersensitivity. Many cases of indurative headache, lumbago, low back pain and intercostal neuralgia are of fibrositic origin, also many cases of "central or interstitial sciatica."^{3 10-1 0 558} In sciatic fibrositis, pain is referred to the hamstring muscles and not to the nerve trunk which is not even tender until later, reflexes are normal and anesthesia and paresthesia are absent.^{102 150} Albee considers myofascitis the commonest cause of pain low in the back where there are so many fascial insertions into bone and "a more sluggish circulatory condition than elsewhere" (But the blood supply of the back is rich—Ed). Panniculitis, a fibrositis of subcutaneous fibro-areolar fatty tissue, is characterized by disseminated superficial pea-like nodules, so that the skin wrinkles or puckers

when grasped between the hands. The tissue is fatty, tender, and bruises easily. Normal fat is not tender or lumpy. These and other features of panniculitis were described by Telling.

Pathology Data thereon are meager because biopsy is not often made, when made it reveals a vague pathologic picture. Information is available concerning the nodules but not concerning the reaction responsible for such varieties as capsular fibrositis. Sections of nodules from early cases of lumbago show, according to Douthwaite, no recognizable difference from the normal surrounding structures. They give the microscopic appearance of normal excised muscle, since they represent a gel or local coagulum with no cellular infiltration, yet "the nodule is a very real thing." Even chronic lesions reveal no characteristic or striking architectural arrangement, like Aschoff nodules, but are vaguely described as "unhealthy fibrous tissue," "inflamed scar tissue" (Copeman). Certain nodules are not tender, hence some ignore them as of no significance, particularly because experienced persons can feel free nodules in "normal persons." They are not normal but, according to May, always evidence of a previous attack of (sometimes subsymptomatic) fibrositis. Even the nontender ones are potentially troublesome.²⁰⁸ They are often difficult for the inexperienced to palpate. Cases of lumbar myofascitis with palpable nodules are in the minority, according to Albee, who failed to find measurable increases of thickness in affected regions. The more severe cases of fibrositis reveal the most nodules, tender or otherwise. They are usually tender, especially when a nerve twig is implicated, often exquisitely so, when they are pressed the patient squirms and muscles go into spasm. To Douthwaite they do not represent septic emboli, if they did, massage would only aggravate the condition. But for the very reason that firm massage of nodules does often produce slight fever and malaise within 24 hours or so, Scott and Wilson believed they must contain bacteria, probably streptococci and toxins, not toxins alone. Even breaking down old hard nodules is likely to produce reactions. (No data on cultures were given.)

(Most American clinicians have been loath fully to recognize "fibrositis," because its supposed pathology is so ill-defined, its symptomatology so subjective, its chemical reactions "normal." Others who recognize it as a distinctive symptom-complex worthy at least of clinical separation, are nevertheless disturbed by its insecure pathologic basis. Those numerous physicians who, particularly in England, continue to write familiarly of the pathology of fibrositis would immeasurably strengthen their position if, instead of merely briefly restating oft-repeated comments, they would present formal studies with microphotographs showing, as well as possible, the vague reactions which are considered so basic. Until then they cannot escape the suspicion of being guilty of merely repeating what they have read. Many have obviously accepted the work of Stockman (1920) but in the past 20 years of English "fibrositology" few if any have formally attempted to corroborate or advance that work.—Ed.)

Laboratory Data The sedimentation rate is generally normal.⁴⁹⁰ Stuart-Harris found no antifibrinolysins. In stools, Albee found "his-

tamine in large quantities", to him an index of toxicity possibly an etiologic agent

(No quantitative data were given—Ed)

Differentiation Slocumb studied 100 patients with periarticular and intramuscular fibrositis, the commonest forms

About 50 per cent of the patients had both types concurrently or consecutively, 25 per cent each had one or the other type alone. Since many cases of periarticular fibrositis are erroneously called "mild atrophic arthritis" (with its malevolent connotations) differentiation is important. The 100 cases of long chronic fibrositis (total disability 284 years, selection being made to allow maximal local and constitutional changes) were compared to 100 cases of atrophic arthritis, early cases being chosen to see how early the local and constitutional differences would be apparent. Both groups experienced fatigue and nervous exhaustion. Ten pounds or more were lost by 47 per cent of the arthritics, by only 7 per cent of the fibrositics. Roentgenograms were "definitely positive" in 86 per cent of the arthritics (although 50 of them had had their disease less than a year), in none of the fibrositics (except those with occasional incidental senescent hypertrophic arthritis). The sedimentation rate averaged 12 mm (1 hour) in the fibrositics (below 16 mm in 73 per cent, never over 32 mm), 72 mm in the arthritics (normal in only 6 per cent, over 25 mm in 91 per cent, over 50 mm in 67 per cent). Rates were usually elevated within the first six weeks of arthritis. Hemoglobin was below 13 gm in only 5 per cent, below 12 gm in only 1 per cent of the fibrositics, below 13 gm in 42 per cent, below 12 gm in 19 per cent of the arthritics. Occasional patients with periarticular fibrositis exhibited one of these abnormalities, very rarely more. Most of the arthritics exhibited two or more definite, not slight, alterations.

In summary, periarticular fibrositis is readily differentiated from even early atrophic arthritis by the characteristic and persistent negativity of clinical, laboratory or roentgenographic evidence of intra-articular disease or constitutional reaction.

Cases of left-sided thoracic intramuscular fibrositis are occasionally called angina pectoris. Some recognize "mural fibrositis" of the abdominal musculature, often mistaken for intra-abdominal disease. According to Wilson, pain referred to the abdomen results particularly when fibrositic nodules involve the eighth to the eleventh intercostal spaces. Motion of these muscles may or may not cause pain. Differentiation often depends on finding tender intercostal nodules, pressure on which produces immediate referred abdominal pain "or an attack of abdominal pain delayed for some hours or even a day or two."

Etiology The cause of primary fibrositis is unknown. The usual conjectures were entertained: infection²⁷⁶, strain and chill^{3, 69, 102, 106, 151}, "metabolic disturbances"^{69, 150}, "toxicity from intestinal infection or poor elimination³," oxaluria²⁷⁶. Generalized fibrositis is probably an infection, chills and strains produce localized fibrositis^{150, 151, 276}.

(Reading current reports we, with Milliken, were "left a bit vague as to whether myofascitis is due to focal infection, the phases of the moon, or the Hoover administration"—Ed)

Treatment For acute fibrositis the majority favored rest and heat. If the patient is brave, Douthwaite recommended, even in acute cases, vigorous motion of the affected part for 20 minutes, "great, sometimes complete relief is obtained in half an hour." In lieu of active motion, massage was given. English writers again emphasized the "supreme importance and curative value" of their favorite remedy, deep massage "to rub away the nodules." "The only effective cure," it is more useful if preceded by heat (Cruickshank). No other treatment is of such value, the fibrotic change must be treated mechanically, treatment may be painful, tedious and prolonged (Telling). "Break down the fibrous nodule and liberate the imprisoned toxins," to be then eliminated by improved circulation. Specially trained masseurs can do this, although it is painful they must persevere and not be alarmed by the patient's easy bruising (Gordon). Hunt approved the continental axiom: no cure without bleeding. "Massage must therefore be progressively stronger and deeper, and may be energetic enough to cause actual hemorrhages around the nodule." Douthwaite also advocated "deep massage which will probably make the patient yell."

When such massage is too painful preliminary histamine ionization may be useful.^{102, 106} Wilson who of all wrote the most enthusiastically and in greatest detail on the technic and value of manipulative massage to break up the fibrotic nodules, claimed that in some cases it "will in a few minutes relieve pain that has for many years accompanied certain movements of a joint." "Localized tenderness can be made to disappear within a few minutes." Because such massage may "produce a liberation of toxin" and a reaction of fever and malaise within 24 to 48 hours, Wilson and Scott advised that a limited number of nodules be massaged at one session, and massage be given only every three to five days. For old nodules too resistant to be "destroyed" by finger pressure, Wilson described a technic utilizing the sharp but protected blows of a wooden mallet. Manipulation and massage under anesthesia may cure certain cases of chronic lumbago "within five minutes," according to Douthwaite.

(From a limited experience with manipulative massage we cannot match the enthusiasm of our English colleagues, but American clinicians must use this treatment more extensively to criticize it authoritatively—Ed.)

Numerous other measures were recommended. Triple typhoid vaccine, streptococcal vaccine, injections of a local anesthetic or even simple needling of a nodule.^{102, 106} Injections of saline or quinine urea hydrochloride⁵⁴⁸, bee-venom^{57, 397}, histamine by injection or ionization^{57, 102, 106, 157, 306, 481}, colonic lavage^{3, 10-, 106}, dietary and medicinal correction of oxaluria, acidophilus milk, warm climate, low carbohydrate diet, a raw vegetable diet²³⁷. Gold is valueless.^{14, 102, 106} (A refreshing statement—Ed.) Scott noted "a more or less complete disappearance of local disability in 18 out of 25 cases" of intractable fibrositis, usually of 10 or more years' duration, from local injections of a "lipovaccine" (streptococci suspended in olive oil) into nod-

ules A local and general reaction like that from heavy massage was induced within a few hours "Persons who had been in poor condition for years regained their normal color and appearance in a week or two", symptoms abruptly subsided, leaving the fibrositic region comparatively painless

To avoid the common local fibrositis in the neck and shoulders presumably caused by wearing too heavy coats, heavy clothing outside and evening gowns inside the house, with consequent trauma and chilling, Burt recommended warm, but light, clothes, and adequate sweating "Skin-toughening cold showers" may be prophylactic³⁶⁰

Dupuytren's Contracture This starts as a firm, fixed nodule in palmar fascia, usually near the base of the ring finger, affects fascia not tendons, and is generally eventually bilateral Of Meyerding's 273 patients, 45 per cent were physical, 55 per cent mental, workers, 88 per cent were males, age of onset was 17 to 80 (av 54) years Of 273 patients with 448 affected hands, both hands were involved in 64 per cent, the right alone in 25 per cent, the left alone in 11 per cent Fasciotomy is generally inadequate Palmar fasciectomy gave "excellent results" in 89 per cent of 117 hands Postoperative treatment included use of splints, heat, early motion, more active physical therapy after the fourth week^{364, 365}

Epidemic Diaphragmatic Pleurodynia The "devil's grip" is spreading westward in the United States epidemics were noted in late summer and fall of 1934 and 1935 72 cases in Illinois³⁶⁸ and 22 in Colorado,⁴⁰¹ the first two west of the Appalachian Mountains and Mississippi River, 11 cases in Cincinnati⁴⁶ and 282 in southwestern Ohio²⁸⁵ A few patients noted prodromes fatigue, vague abdominal cramps Onset was usually abrupt, with sudden, severe pain in the region of the diaphragm (more often on its thoracic than its abdominal side), lower thoracic wall, often the entire costal margin, also in the epigastrium and upper abdomen Pain shifted from side to side and came in repeated paroxysms (two to nine in all) Sometimes present was pain in back, shoulders, head and neck Other symptoms were fever (100° to 104° F), rapid pulse, leukocytes 3000 to 10,000, no eosinophilia, pallor, nausea, sweating, occasional diarrhea and chill Deep breathing was painful Pain and fever lasted 24 to 36 hours, occasionally three or four days, maximal pain was often between the fourth and twelfth hour The third paroxysm was usually the most painful After three or four days of quiescence a second short attack may appear Friction rub was generally absent (often present in European cases) When abdominal pain is severe, differentiation from "acute abdomen" is difficult, pain may be over McBurney's point but is generally higher and bilateral, the abdomen is fairly relaxed The condition is also mistaken for pleurisy, herpes zoster, coronary thrombosis Recovery was usually rapid and complete Complications were rare (orchitis once)³⁶⁸ Treatment is symptomatic, morphine is required The cause is unknown Small's (1924) plasmodial theory was not confirmed The disease is communicable incubation period being

three to seven days. Blood cultures in six cases were sterile, biopsy of the latissimus dorsi muscle was "negative" ⁵⁶⁷. Age, sex and social status seemed unimportant. Because it occurs in the mosquito season and nearly every one of his patients recalled a recent mosquito bite, Naugle suspected a mosquito-borne disease.

Myositis Ossificans Commonest sites for the traumatic form are the brachialis anticus from injuries about elbow, the quadriceps femoris from "Charley horse," the abductor muscles in horsemen, the deltoids in infantrymen from gun-butt trauma, and the biceps brachii. Hobart noted nine cases. Hamada treated a young girl with myositis ossificans progressiva multiplex.

Calcified Intramuscular Parasites These, presumably cysticercus cellulosae, produced countless discrete, ovoid shadows $\frac{1}{8}$ to $\frac{1}{2}$ inch in size throughout the extremities, abdomen, chest. Muscle biopsy was refused (Lesoff and Schulman).

Trichinosis Asymptomatic trichinous myositis must be very common. At necropsy, McNaught and Anderson found living larvae in 24 per cent of 20 human diaphragms from persons aged 2 to 87 years. The number of larvae was less than 20 per 50 gm of muscle in 79 per cent. No patient had had clinical trichinosis.

Melitensis Infection of Muscle A case of degenerative myositis with temporary muscle atrophy from Malta fever was noted (O'Donoghue and Scott).

Myopathies and Neuromuscular Disorders Further studies on metabolism of creatine and creatinine in myopathies were presented ^{247, 366}, also electromyographic studies in hysterical torticollis, Huntington's chorea, paralysis agitans ³⁴⁶. The use of amino-acetic acid (glycocoll, glycine) was recommended not only for primary myopathies but also to relieve fatigue and creatinuria of muscle disturbances secondary to such conditions as nephritis, scarlet fever, hyperthyroidism, anemia, hyperinsulinism (Terhune and Green).

DISEASES OF BURSAL

The four intermetatarsophalangeal bursae have been ignored in literature. bursitis in one was noted ³⁴³. In Snodgrass' case of compound cystic bursitis of a knee, the suprapatellar bursa and that in the gastrocnemius muscle were connected and both enlarged.

Subdeltoid and Subacromial Bursitis Of the 140 bursae in the body (33 in each upper, 37 in each lower extremity) the subdeltoid is most often diseased (Echtman). Of 300 consecutive painful shoulders studied by Haggart and Allen 80 per cent were caused by subacromial bursitis, 6 per cent by arthritis, 8 per cent by myofibrositis, 6 per cent otherwise. In Lee's cases, trauma seemed to be a factor in 50 per cent, the right shoulder was affected twice as often as the left, 75 per cent of patients were males. Many cases of Weeks and Delprat were preceded by upper respiratory infections. Current ideas on etiology, differential diagnosis and therapy were reviewed.

Echtman first applied cold applications, then heat, massage and manipulation, diathermy for cases with calcification, for stubborn cases galvanization or ionization with magnesium sulphate. Lee used immobilization in abduction and external rotation, surgical removal of chronic painful calcium deposits. Lattman stated that roentgen therapy relieves pain and restores function faster than anything else; good results were noted in 15 of 20 cases, one or two treatments reputedly relieved pain in 24 to 48 hours. Rapid relief may follow simple aspiration of bursal fluid, even the mere procedure of needling (multiple punctures at one session) is often helpful whether calcium deposits are present or not (Weeks and Delprat). Haggart and Allen advised for acute bursitis exploration and drainage of the calcified material or procaine injection, for chronic bursitis, physiotherapy, exercises (diagrammed), occasionally procaine injections, for chronic adhesive bursitis, drainage of calcified material, manipulation to loosen adhesions, or procaine injections, physical therapy, exercises. The latter cases without calcification may need elevation and traction in a Balkan frame.

(Calcium deposits often rapidly disappear spontaneously. Their surgical removal should be advised with caution—Ed.)

OTHER STUDIES

Articular Roentgenography The "articular space" as referred to by roentgenologists is a misnomer, it is not the true space but translucent interosseous material, cartilage and ligaments. With improved technic, Widmann and Stecker visualized the true articular space in normal knees and shoulders, not elsewhere. Friedman described an improved roentgenography to show hip joints laterally.

Arthroscopy Further observations on the technic and value of arthroscopy and punch biopsy were reported (Burman, Mayer and Finkelstein). The procedure was technically successful and caused little or no articular reaction, but diagnoses on specimens obtained at biopsy did not always conform to those later made at surgical operation.

Articular Function A method for measuring and recording joint function was described (Cave and Roberts). Jones applied engineering principles to the study of human joint lubrication and determined coefficients of friction of interphalangeal joints. The usual form of lubrication of human joints is by a fluid film which survives a load which can crush bone.

Articular Physiology The metabolic requirements of articular tissues must be known before one can properly discuss the problem of articular nutrition. Bywaters studied the metabolism of normal and abnormal cartilage and synovia.

Cartilage possesses slight but definite glycolysis which, per cell, is similar to that of rabbit liver or kidney. The CO₂ present all comes from lactic acid. Glycolysis was inhibited by fluoride, increased by phosphate. Oxygen consumption of cartilage was small but greatly increased by methylene blue. The metabolism of synovial

membrane is about the same as that of other adult tissue. Transformations affected by synovia seemed similar to those of ordinary connective tissue except for its very low respiratory quotient for which there is no comparable figure. Inflamed villi have an increased metabolism out of proportion to cell increases. The metabolism of cartilage and synovia is similar in humans and horses. The cartilage metabolism of a horse with degenerative arthritis, and of a woman with atrophic arthritis was normal. Synovial fluid contains twice the amounts of glucose necessary for cartilage.

(For a better understanding of articular diseases many such studies are necessary—Ed.)

The growth mechanism of articular cartilage as seen in animals of various ages, involves cell division, mitotic in the young, amitotic in older ones. Elliott regarded amitosis an active process of tissue proliferation, not the result of mechanical insults, degeneration or mere necessity of increasing nuclear surface.

Further studies were made on the rôle of the reticulo-endothelial system in the deposition of colloidal and particulate matter in articular cavities (Kuhns and Weatherford). Colloidal and particulate matter is carried by blood to joints from various body tissues, skin, the gastrointestinal tract. It is stored chiefly in histiocytes in synovia, also in bone marrow, lesser amounts in intermuscular septa and articular fat pads. Mild inflammation in joints increases the deposition of such transported substances. Local blocking of the reticulo-endothelial system is transitory, incomplete, and ineffective in preventing deposition of colloidal and particulate matter in joint tissues.

Muscle Physiology Studies on electrolyte changes in muscles during activity¹⁷¹ and on the circulation in striated and plain muscles in relation to activity⁶ were reported.

Physiology of Tendons Cronkite studied the tensile strength of 294 human tendons from cadavers and autopsy material. Certain errors of technic were inherent in methods used. Tensile strength ranged from 8700 to 18,000 pounds per square inch of surface. Right- and left-sided tendons did not vary in strength, nor did flexor or extensor tendons of hands. No one tendon in the body was consistently strongest. There was no correlation between tensile strength and age or cause of death. A historical note on the origin of the term "tendo Achilles" appeared (Couch).

Additional Of interest also were studies by Steindler on physical properties of bone, by Biernan on skin temperature as affected by various physical and chemical factors: age, fever, disease, heat, cold, anesthesia, drugs, tobacco, whiskey, humidity, air motion.

CAMPAIGN AGAINST RHEUMATIC DISEASES

The caliber of much of the work reported herein permits one to agree with Weil that rheumatology is no longer "that cloaca of ignorance" so scornfully referred to by Haygarth. The brightest side of rheumatism is the growing interest physicians are taking in it. They realize the necessity

of meeting its challenge instead of sidestepping it.¹⁸⁸ Often the family physician, working with consultants and social agencies, will find at hand adequate facilities for managing his arthritic patients. But the army of arthritic and cardiac cripples attests the inadequacy of our attack. Although in the United States there are more cases of chronic arthritis and "rheumatism" than of cancer, tuberculosis and heart disease combined and although almost every state and county has a special institution or other facilities for treating tuberculosis, not a single county or state in the United States has a special institution for the care of arthritics except Boston which has the Robert Brigham Hospital.

(However, many hospitals and clinics have departments for the special study and care of arthritics—Ed.)

From a survey of 89 hospitals, Kling concluded that none of the institutions, city or county, general, church, university or even orthopedic hospitals, are extending adequate facilities to arthritic victims. All gave very low admission rates for arthritics (0.85 to 2.3 per cent). There are about 646,000 tuberculous patients in the country of which 363,000 are bedridden. To the 87,000 beds available for them, about 156,000 tuberculous patients are admitted annually. In other words, one of every four sick or one of every two bedridden tuberculous patients is provided with institutional care, generally for the duration of active disease. In contrast, hospital facilities were available for less than 10 per cent (98,000) of our 1,020,000 bedridden rheumatic patients. About 90 per cent of beds for the tuberculous are free, very few free beds are available for arthritics. Physicians in charge of tuberculosis devote themselves largely to this disease, but most rheumatic patients are cared for by "physicians with little interest and very inadequate facilities." There is therefore great need for state sanatoria or community funds for hospitals and teaching centers to care for and rehabilitate those persons unable to attend spas and health resorts, and to allow study of all aspects of these diseases.^{181, 269, 3-9} But to avoid a narrow viewpoint, rheumatism centers should be established in connection with general hospitals and general clinics, not as segregated institutions for arthritis (Irons).

In England also the few existing facilities merely touch the fringe of the problem, which must be attacked as was that of tuberculosis. England must have a changed outlook, and realize that rheumatism although chronic, is an acute problem (Elman). In that country the disease is largely unchallenged. The Red Cross Society Clinic in London is "the only one in England solely devoted to treating rheumatic diseases." Copeman reviewed its activities. 80,000 to 90,000 patients (visits or registrations?) are seen yearly. "Every city and industrial center in England should be a candidate for such a clinic." Other angles of the campaign were outlined in Horder's report of the activities of the British National Society for the Control of Arthritis, and in Van Breemen's report of the organization, function and aims of the International League against Rheumatism.

Denmark and Sweden are courageously facing the problem Kahlmeter regarded the value of Sweden's specialized hospitals self evident Various other methods were adapted to bring rheumatic diseases under control institutions for research and for the training of rheumatism specialists, consultation clinics for rheumatic patients allied to hospitals and physical therapy units, proper development of spas, utilization of social service departments

Noting the meager instruction on joint diseases given to medical students, Johnson believed instruction should be the duty of clinicians But clinicians already have too large a share of the curriculum and have inadequate hospital material to present because hospitals are so niggardly in the admission of arthritic patients Orthopedists, with their abundant (if late) material, should therefore accept the duty and welcome the opportunity to "become physicians again" The rheumatic problem should be taught in four ways by lectures, ward classes, dispensary services, and in the libraries and laboratories It should be taught, not dogmatically, that is not safe, not by an advocate of any one theory, one may be pleading a bad cause, not by an experimenter, that is too complex for the student It should be taught by the philosopher with a broad dispassionate viewpoint, by one who above all else avoids the semblance of authority

AN ARTICLE CONTRIBUTED TO AN ANNIVERSARY VOLUME IN HONOR
OF DOCTOR JOSEPH HERSEY PRATT

A RARE MANIFESTATION OF GOUT, WIDESPREAD ANKYLOSIS SIMULATING RHEUMATOID ARTHRITIS *

By ALFRED O LUDWIG, GRANVILLE A BENNETT, and WALTER BAUER,
F A C P, *Boston, Massachusetts*

ANKYLOSIS may occur in gout. Such ankylosis results because of monosodium urate deposits in the articular tissues. The presence or absence of ankylosis in gout is dependent upon the extent of the urate deposition, its location and the reaction of tissues involved. Ankylosis in gout, however, is rare. When it does occur, it is usually limited to one or two joints, most commonly the small joints of an individual 40 or more years of age, who has been the victim of gout for a long period of years^{1, 2, 3, 4}. Most of the references concerning ankylosis in gout are to be found in the writings of the latter half of the last century. All too frequently, it is merely mentioned without describing the pathological changes encountered.⁵ Others^{6, 7, 8, 9, 10, 11, 12, 13, 14} have described in detail the articular changes resulting from gout. Virchow, as early as 1868, reported a case with complete ankylosis of the terminal phalangeal joint⁶ of the great toe. Rarely is widespread ankylosis mentioned, although Litten¹⁵ reported such a case in 1876.

The present case is sufficiently rare to justify a published account because of (1) The relative youth of the patient, (2) the severity of the gout, (3) the rapidity with which extensive intra-articular changes resulting in widespread ankylosing deformities occurred, and (4) the clinical picture presented by the patient, which when first seen so closely simulated that of an individual with extensive rheumatoid arthritis.

CASE REPORT

F N, a white, single, native-born salesman, aged 28 years, was admitted to the medical wards of the Massachusetts General Hospital on December 17, 1934.

Family History There was no known occurrence of gout or arthritis in the patient's relatives. His father, a very obese man, died of a cerebral hemorrhage at the age of 50.

Past History The patient had never been ill except for attacks of measles, chicken pox, mumps and influenza, all without any complications. He had injured the arch of his left foot playing foot-ball some years before the onset of the present illness. This resulted in chipping of one of the small bones of the foot. The bone

* Received for publication August 16, 1937.

chips were removed in 1925. He had been an individual of extremely good habits and had always been fond of athletics prior to the onset of his present illness. He used neither alcohol nor tobacco.

Dietary History His diet had always been very adequate and well balanced in every regard. His consumption of meat had been normal. He habitually ate liver once a week, but did not ordinarily indulge in foods of high purine content such as brains, kidneys, or sweet-breads. He did not use chocolate or cocoa.

Present Illness In February 1927, at the age of 21, he had his first attack of arthritis. The onset was sudden, without preceding infection or other prodromata such as one frequently observes in rheumatic fever, rheumatoid arthritis, or gonorrheal arthritis. He first noticed severe pain in the left ankle with marked swelling and redness. It was exquisitely tender. There was an associated fever. The right ankle, both knees and both hips were subsequently similarly affected. The arthritis was migratory in nature, tending to clear in one joint (but never completely) before another joint became involved. With subsidence of the swelling, desquamation of the skin overlying the joint occurred. The total duration of the attack was four to five weeks, following which all joint signs and symptoms gradually disappeared. He made a complete recovery without any residua. He had received only symptomatic treatment. A tonsillectomy was done in April 1927, as a preventive against future attacks. Shortly afterward, he was accepted for life insurance.

He remained absolutely symptom-free and apparently well until March 1928, when he suffered another attack of acute arthritis, almost an exact duplicate of that of the year before in that it was of sudden onset, polyarticular and migratory in nature, with associated fever. The same joints were involved. This attack lasted four to five weeks and was again followed by complete recovery. Recovery from this self-limited attack was credited erroneously to the use of several intravenous injections of orthodoxy-benzoic acid.

In 1929, he experienced a similar attack of arthritis again followed by a year of complete freedom. He suffered from a recurrence in 1930 during which he had involvement of the shoulders, elbows, wrists, and fingers for the first time. Injections of "serum" were given without benefit. This attack lasted about the same length of time. He again made a complete recovery, but had two similar attacks of arthritis that same year.

During the next two years, he had two or more such attacks. In 1932, he had dysuria on one occasion following which he passed a small amount of gravel (probably small urate stones). This same year, he noted increasing stiffness of the ankles. Since then, he has had to use a cane or crutches for walking. In 1933, his right wrist and several fingers became stiff. During the 12 months prior to admission he had four attacks of arthritis. These had occurred in November 1933, March 1934, September 1934, and November 1934. The last of these attacks which began three weeks prior to entry caused him to seek further medical aid. The onset had been sudden and was marked by swelling, redness and pain of the ankles, wrists, knees, hips, shoulders, elbows, wrists and fingers. Following each of these last-mentioned episodes, there was increasing stiffness and deformity of the joints involved. The temporomandibular and vertebral joints had never been involved.

The patient had been on a high vitamin-low carbohydrate diet since 1931. This was without effect on the joint symptoms but did result in a 45-pound weight-loss.

COMMENTS ON HISTORY

This case history is of importance in that it illustrates many diagnostic points characteristic of the gouty patient and his arthritis as well as some of the unusual features of this particular case.

In attempting to make a correct diagnosis in the case of patients suffering from joint disease, an accurate history is most important. A detailed history will enable one to suspect the correct diagnosis in the majority of the cases. In the remaining few, a complete physical examination and one or two well chosen diagnostic laboratory tests are needed. In an occasional patient, a biopsy may be necessary and most helpful. In rare instances, the passage of time and further observations are indispensable.

In recent years, Hench^{16, 17, 18} has tried to make the physicians of this country gout-conscious. In attempting to do so, he has repeatedly stressed as have others^{19, 20, 21, 22, 23, 24, 25} in the past the importance of an accurate history. In many instances it alone is sufficient to make a "presumptive" diagnosis.¹⁶ Certainly a suspicious history should always call for a therapeutic test with colchicin. If marked or complete relief always ensues 24 to 72 hours after the onset of colchicin toxicity symptoms, the diagnosis is for practical purposes established. This therapeutic diagnostic test can and should always be carried out even if uric acid determinations are not possible.

In this particular case, the history of recurrent attacks of arthritis, with absolutely complete freedom from joint symptoms between each attack for a period of five years before any permanent joint changes took place, is of itself highly suggestive that the patient had suffered from recurrent gouty arthritis which had finally become chronic.

Recurrent polyarticular, migratory arthritis with associated fever in a young adult would naturally suggest the possibility of recurrent or cyclic rheumatic fever. In this case, however, there were no preceding upper respiratory infections nor any of the other precipitating factors occurring some 7 to 14 days prior to the onset of each attack of arthritis which are so frequently observed in rheumatic fever. None of the associated symptoms of rheumatic fever such as weight loss, skin eruptions, nodules, nose bleeds, tachycardia, precordial pain, etc., was present. Furthermore, with migration of the arthritis, the previously affected joints did not clear so promptly as they regularly do in rheumatic fever. There were no symptoms suggestive of heart disease such as one might rightly expect in a patient who had had so many recurrent attacks of rheumatic fever.

Polyarticular involvement occurs in about 5 per cent of all cases of gout.¹⁶ The younger the individual, the more likely it is to be polyarticular. The polyarticular involvement may be simultaneous or of the migratory type. This form of gout rarely involves the large toe and the attacks are of long duration, usually weeks instead of 7 to 10 days. The fever is more marked and may last weeks. This type is rarely afebrile.²⁵ It signifies severe gout. It is frequently misdiagnosed rheumatic fever.

A specific infectious arthritis due to the gonococcus is sometimes characterized by recurrences. We have seen one individual who experienced eight such recurrent attacks of arthritis due to a latent focus. In such instances, the story is quite characteristic. There is usually an exacerbation or

recurrence of the genito-urinary symptoms. Particularly is this true in the male. On the same day or a few days later, the patient experiences a chill or chilly sensation followed by fever and migratory aches and pains or a migratory arthritis. This usually subsides after a day or two, leaving one or two joints involved which may show mild or severe inflammatory signs with a corresponding amount of joint pain, etc. Rarely does it remain polyarticular. Although the swelling and other signs of inflammation may be quite severe, they are rarely of the same severity as those seen in gout, where the swelling is more marked, extending further beyond the joint margins than in any other type of arthritis, with the possible exception of certain cases of septic arthritis. Acute gouty arthritis more nearly resembles septic inflammation or extensive cellulitis. There may be an associated lymphangitis. In gouty arthritis, the pain is severe, often described as crushing, worse during the night, letting up in the early morning. The patient protects the joint in every way possible. The overlying skin is red, tense and shiny. The superficial veins are markedly distended. The tenderness is exquisite. As the tenderness subsides, pitting edema is demonstrable. With disappearance of the joint swelling, desquamation of the cuticle and itching follow.

Rheumatoid arthritis in 18 per cent of the cases is characterized by an atypical onset and in 7 per cent may remain atypical for some time, hence the more appropriate name atypical rheumatoid arthritis³². This is the group which is all too frequently labelled focal infectious, toxic or non-specific infectious arthritis. The first attack is often acute in onset in an individual who had previously considered himself well. These patients are usually robust and not the asthenic type of individual with evidence of increased vasomotor activity, etc. The attack may or may not be associated with an acute infection or an obvious focus of infection. The joint involvement is usually asymmetrical. It may be polyarticular and migratory. The monoarticular form is encountered. Recovery from the first attack may be complete and if so is often ascribed to some therapeutic procedure whereas it truly represents the first self-limited attack of an acute, atypical rheumatoid arthritis followed by apparent recovery. The remission following such an attack is variable. It may be of only a few months' duration, occasionally a year. However, in most instances, it will eventually be followed by a relapse. An individual may have a number of such recurrences and remissions before the disease becomes chronic. As a rule, the remissions are not complete. Frequently there remains certain tell-tale evidence of the previous joint involvement. Rarely if ever will one encounter a case of rheumatoid arthritis with a history similar to that of the patient herein described, of 12 or more acute attacks of arthritis each followed by absolute and complete recovery without residual joint deformity. The marked joint signs, subsequent desquamation, itching, etc., seen in this case are not encountered in atypical rheumatoid arthritis. At

the stage of atypical rheumatoid arthritis where many joints are deformed one will usually find that the joint involvement, particularly of the small joints, is symmetrical.

The typical case of rheumatoid arthritis with preceding constitutional, vasomotor and neurological symptoms, insidious in onset, characterized by symmetrical joint involvement (usually the small joints), should rarely if ever be mistaken for any type of gouty arthritis. In cases with chronic joint deformity with ankylosis due to gout, tophi and other evidence of the disease will be present.

The eliciting of a history of renal colic with the passage of a stone or gravel in an individual suffering from recurrent arthritis should always lead one to suspect gout as the cause of both symptoms.

This patient is of further interest because of the early age (21 years) at the time of onset of his gouty arthritis. The average age of onset has been recorded as 40 years^{16, 25}. Pratt states that the youngest case he saw with tophi was a man of 28 years²⁵. He further states the disease seldom develops before 20 years of age. One patient observed in this clinic may have had his first attack at nine years of age (it was diagnosed tuberculosis of the hip at that time and he was treated with plaster casts). From the ages of 14 to 19 he had numerous recurring attacks of polyarticular migratory arthritis accompanied by fever. They were always followed by complete recovery. They had always been diagnosed rheumatic fever although he had no endocarditis. When first seen at 19 years, he had a whole blood²⁶ hyperuricemia of 9.2 mg per cent. It has continued to run between 12.3 and 14.8 mg per 100 c.c. serum^{26, 29, 30}. He has since developed tophi (age 20 years). Undoubtedly such cases of gout are frequently mislabeled rheumatic fever because of the youth of the patient and the close similarity to rheumatic fever. Such mistaken diagnoses can be avoided if we will become gout-conscious. Repeated careful questioning at each visit will often result in the patient being able to recall earlier attacks which he had failed to mention at the time of his first visit. Such attacks frequently follow slight athletic injury, and are diagnosed sprain or strain, although the severity and duration of symptoms are consistent with a monarticular form of gouty arthritis.

In this instance, there was no family history of gout. There can be little doubt that the frequency with which data indicating heredity are obtained depends upon the degree of thoroughness of the inquiry. Again oft-repeated questioning on subsequent visits plus repeated questioning by the patient of his relatives will result in positive information which had been denied previously.

This patient knew of no precipitating factors. He did not consume excessive quantities of high purine foods and his attacks did not follow gastronomic sprees. We were unable to elicit evidence of attacks following major or minor physical trauma, such as fractures, dislocation, injury

wearing of tight shoes, after unusual use of a joint, etc,¹⁷ nor did they follow "physiologic trauma" resulting from protein therapy, severe purging, loss of blood, exposure to cold and wet, etc.¹⁷ He thought worry might have contributed.¹⁷ Such precipitating factors should always be sought. In this case neither of the patient's operations induced an attack.¹⁷ Hench has repeatedly stated "*suspect gout in cases of acute postoperative arthritis particularly in males*"¹⁷ This warning is well worth remembering. Operative procedures may also induce an exacerbation of rheumatic fever. In such instances there is the usual latent period of seven to 14 days between the operation and the onset of the arthritis. Although rheumatoid arthritis is frequently followed by immediate improvement, usually shortlived, following surgical procedures, it is occasionally activated or increased in severity. This is probably an effect of the ether anesthesia and not due to the removal of an obvious focus of infection.

The prodromata preceding an attack of gouty arthritis are variable. Some state that they feel their best before each attack, others complain of nausea, indigestion, melancholia, polyuria, nocturia, stiffness, aching, etc.

FIG 1 This schematic chart depicts the frequency of the recurrent attacks of acute disabling gouty arthritis experienced by this patient. It will be noted that one such attack occurred each spring for the first four years. They then increased in frequency. Residual joint changes were present after the first five years. (Each peak represents an attack. The solid black area from 1932 on indicates the approximate disability present.)

From figure 1 it will be noted that the attacks first came once a year, usually in March or April. More attacks occur between April and June than at any other time of the year.¹⁷ After four years, the frequency of attacks increased to two to four per year and at the end of five years, the patient had residual joint deformity. The time between the first and second attacks is variable. It may be months or years. In 100 cases, the patients averaged one attack every 1.7 years.¹⁶ The average for each attack was 13 days. The interval between attacks becomes less with each subsequent attack until chronic joint deformity becomes evident. To have as marked crippling at the end of five years as was noted in this case is most unusual. Such marked crippling is more apt to be seen in the polyarticular form and represents the more severe type of gout. Only 2 per cent of cases of gout are chronic from the onset.¹⁶

An important thing to remember is that gouty patients feel unusually well between their attacks, as one patient stated, "my arthritis is almost

FIG 2 This anterior view of the patient shows the degree of disability present at the time of entry. He had to support himself because of the flexion contractures of the knees and the ankylosed ankles. The equinus deformity of the left foot is apparent. The manner in which he grasped the measuring stick and cane serves to illustrate the deformities of the elbows, wrists and fingers.

unbearable, yet between attacks, I am as fit as a fiddle" The attacks of arthritis are self-limited Many of the so-called specific therapeutic measures for rheumatoid arthritis such as vaccines, sera, colloidal injections, removal of infected foci, colonic irrigations, endocrine therapy, etc., are prescribed and erroneously given credit for curing an attack of rheumatoid arthritis, whereas the patient was suffering from a self-limited attack of gouty arthritis

PHYSICAL EXAMINATION

The patient was examined on December 17, 1934 He was a fairly well developed, moderately obese young man (figure 2) The skin of the hands was cool and moist There were erythematous patches on the skin of the cheeks and forehead, with scaling of the forehead Brownish pigmentation of the skin was present over the dorsum of the hands and feet, the fingers, and the toes Over the interphalangeal joints of the fingers, the skin was dry and scaling The eyes, ears, nose, throat and sinuses were not remarkable The tonsils were out The teeth and gums were in good condition The lungs were normal to percussion and auscultation The heart was normal in size, the sounds of good quality, the rhythm regular, and there were no murmurs The systolic blood pressure was 124 millimeters of mercury, diastolic 90 Examination of the abdomen revealed no abnormality The knee joints were difficult to obtain, other reflexes could not be tested because of the extensive joint involvement The prostate was normal Prostatic massage yielded no secretions

There was a lesion resembling a tophus on the left ear Nodular enlargement of the left olecranon bursa was present There was a suggestion of beginning subcutaneous tophi over the terminal phalangeal joint of the right index finger (figure 3A)

Examination of the Joints All the finger joints were affected. There was a slight flexion deformity of the terminal phalanges of the second, third, fourth and fifth fingers of both hands. The interphalangeal joints of the right second, third and fourth fingers were ankylosed in a position of 10° hyperextension. The left second, third and fourth fingers were similarly involved (figure 3A). There was slight flexion of the left fifth interphalangeal joint. Ankylosis, with slight flexion deformity, and subluxation of the interphalangeal joint of the left thumb were noted

Fig 3 B

Fig 3 C

There was tenderness and limitation of motion of the metacarpophalangeal joints on both sides, more marked on the left. The grip of the right hand was poor, and there was inability to flex the fingers. The grip of the left hand was fair. The skin over the finger tips was atrophic. There was marked atrophy of the interosseous muscles of both hands. Lateral pressure applied to the palms proved to be painful on both sides. The right wrist was completely ankylosed in 35° of flexion. The elbows could be fully flexed, but they lacked 10 to 15° of extension. There was no limitation of motion in the shoulders, although pain resulted with extremes of motion. The dorsal and lumbar spine showed very slight limitation of motion in all directions. The cervical spine was normal. The sacro-iliac joints were normal. The temporomandibular and sternoclavicular joints were uninvolved. There was about 40 per cent limitation of motion in all directions in both hips. The right knee was limited in motion. It lacked 30° of full extension. Flexion was possible to an angle of 60° . The left knee lacked 15° of full extension, and could be flexed only to about 60° . The quadriceps pouch insertion was thickened on both sides. Grating was palpable on motion of both knees. The patellae were not movable. Synovial thickening and irregularities of the articular margins of the knees could be detected on palpation. The left ankle was nearly completely fused in 10° of extension, only a jog of motion

being present in any direction. Motions of the right ankle were markedly limited. Both feet were almost completely fixed. Lateral pressure applied to the metatarsophalangeal joints was painful. Only slight flexion or extension of the toes was possible. All of the toes deviated laterally.

COMMENTS ON PHYSICAL EXAMINATION

The admission diagnosis was chronic infectious or rheumatoid arthritis. The diagnosis of rheumatoid arthritis after complete physical examination seemed justified because the patient exhibited many of the features commonly encountered in this disease, increased vasomotor activity, brownish pigmentation of the skin of the hands and feet, widespread joint involvement with extreme ankylosis (figure 2), the characteristic appearance of the hands and fingers (figure 3A) (shiny atrophic skin with hyperextension and flexion type of deformities of the fingers) and supposed rheumatic nodules in the olecranon bursa (figure 4). However, subsequent examinations revealed a suggestive tophus in the left ear (figure 5). Dissolving

FIG 4 Photograph of the left olecranon bursa. It contained numerous, hard, nodular tophi.

the material obtained from this lesion with hydrochloric acid revealed uric acid crystals. The material gave a positive murexide test. This finding led to the suspicion that the olecranon bursa and the swelling over the terminal phalangeal joint were also tophi. Subsequent examination of material obtained from them confirmed this suspicion.

If one suspects gout, he should make a diligent search for tophi. Subcutaneous tophi are most commonly found in the helix of the ear. They are white, cream-colored, or yellow, varying in size from that of a pin head to a pea. Except in severe gout they rarely appear before 10 years¹⁶

FIG 5 Tophus seen in the right ear

They are pathognomonic of gout but should never be considered such until the monosodium urate crystals have been demonstrated or until a positive murexid test is obtained. They are also found in the cartilage of the nose, along the tendons of fingers, hands, toes and feet and the patellar tendons, patellar and olecranon bursae. The last-mentioned should not be confused with the bursal and subcutaneous nodules of rheumatoid arthritis (figure 6) or rheumatic fever. When the skin overlying a tophus breaks down, a mixture of chalk and water is discharged. The old discharging tophi contain hard chalk-like material.

*Although gout commonly affects the big toe, it does so in only 54 per cent of the cases in the initial attack*¹⁶. As can be seen from this case, almost any joint may be involved. This is true whether the arthritis is mono- or polyarticular. Evidently the spine and sacro-iliac joints are rarely involved. Joint effusions do occur. The temporomandibular and sternoclavicular joints, relatively frequently involved in rheumatoid arthritis, are rarely affected in gout.

If the initial examiner had been gout-minded, he would not have overlooked the ear tophus and would have correctly interpreted the olecranon bursitis.

INTERPRETATION OF ROENTGENOGRAMS

December 1934 Roentgenological examination showed extensive changes in most of the joints examined. The joint spaces of the middle phalangeal joints of all the fingers were narrowed. Irregularity of the articular surfaces was present in the

FIG 6 Rheumatic nodules in the olecranon bursa of an individual suffering from rheumatoid arthritis. The nodules had been present for one year.

middle phalangeal joints of the little fingers, the left being fused (figure 7). Similar changes were seen in some of the terminal phalangeal joints of both hands (figure 7). There was gross destruction and deformity with partial dislocation of the first and second left metacarpophalangeal joints. The right wrist showed irregularity of the joint surfaces with narrowing of the joint spaces. The changes in the left wrist were slight. There was narrowing of the joint space of the elbows. The film of the pelvis showed irregularity and indistinctness of the outline of the left sacro-iliac joint. There were marked hypertrophic changes about the right knee (figure 8). An anteroposterior view of the left knee showed narrowing of the joint space (figure 8) (due in part to the flexion deformity). There were small irregular areas of decreased density in the central portion of the articular surfaces of the femur and the corresponding area of the tibia. The feet and ankles showed changes similar to those seen in the wrist and finger joints (figures 9 and 10). There was calcification of pelvic and leg vessels.

Diagnosis All of these changes were thought to be consistent with infectious arthritis. The hypertrophic changes in the knees were interpreted as being secondary to a previous infectious arthritis.

March 1936, 16 months later At this time the joint changes mentioned above were found to be more extensive. The narrowing of the joint spaces had increased. There was more new bone formation and the deformity of joint surfaces was more

FIG 7 Roentgenograms of the hands, showing decalcification of the bones of the fingers in the region of the joints. Narrowing of many of the phalangeal joint spaces is present. Similar changes are present in the terminal phalangeal joints. Irregularity of the articular surfaces of the middle phalangeal joints of the little fingers is seen, the left being fused. The punched-out area in the distal end of the phalanx of the right second finger appeared in one year's time. There is marked destruction of the metacarpophalangeal joints of the first and second left fingers. The distal end of the phalanx of the right third finger is amputated. The right wrist shows irregularity of the joint surfaces and narrowing of the joint spaces.

FIG 8 Anteroposterior and lateral views of the right knee, showing some decalcification of the bones, narrowing of the joint space and marked marginal overgrowth of the femur and tibia.

marked. The distal extremity of the right third finger had been amputated (surgical) (figure 7). There was partial fusion of some of the tarsal joints. There was obvious destruction and deformity of both the first as well as the second left metatarsophalangeal joints. Localized punched-out areas were present in the bones of

FIG 9 Anteroposterior roentgenogram of the feet demonstrating decalcification of the ends of the phalanges and joint narrowing. Areas of destruction and punched-out areas are present in the bones of both the first metatarsophalangeal joints.

the distal extremity of the middle phalanx of the right index finger, and adjacent to both first metatarsophalangeal joints (figures 7 and 9), as well as at the superior margins of the left os calcis. There were similar but less marked areas of destruction in the metacarpophalangeal joints of the left first and second fingers, the right fifth finger, and the proximal phalangeal joint of the fifth finger. Bone atrophy was present to a marked degree in the bones of the ankles, moderate in the hands and feet. There was some soft tissue thickening about the joints showing bone destruction. The disease was symmetrical in character, several of the phalangeal, metacarpophalangeal and metatarsophalangeal joints being normal. There was calcification of the blood vessels in the lower extremities.

Roentgen-ray examination of the teeth showed unerupted upper third molars, and several malposed teeth. Roentgen-ray study of the sinuses, lungs, heart, abdomen, colon, kidneys and gall-bladder revealed no abnormalities.

COMMENT ON ROENTGEN-RAY INTERPRETATION

The roentgen-ray findings suggestive of gout are punched-out areas, usually 5 mm or greater in diameter, most commonly located in the subchondral bone of the base or head of the phalanges of the hands and feet. Such changes may be late in appearing. In Hench's series,¹⁶ 19 cases with tophi and hyperuricemia had had their disease 28 years or longer and yet

no roentgenographic changes were present. Marginal hypertrophy of the bones involved is a frequent finding. These subchondral punched-out areas are not to be confused with those seen in hypertrophic arthritis and rheu-

FIG 10 Lateral view of the left foot showing the marked decalcification, destruction of joint surfaces, and ankyloses

matoid arthritis. In the latter, generalized decalcification is usually present. Occasionally similar findings are encountered in the case of the gummata of syphilis, leprosy and yaws as well as in tuberculosis and sarcoid.

In this case the roentgen-ray findings were most misleading because of the widespread involvement, marked destruction and deformity, decalcification of the bones of the involved joints and obvious ankylosis. These changes resemble more nearly those of a specific infectious arthritis or rheumatoid arthritis. Marked hypertrophic changes at so early an age are most commonly secondary to a preexisting rheumatoid or specific infectious arthritis. These joint diseases, we should bear in mind, do cause sufficient joint damage so that subsequent wear and tear changes in these altered structures lead to premature development of well marked hyper-

trophic changes Without the clinical history, the roentgenologist could not be expected to make the correct diagnosis

The finding of arteriosclerosis at the age of 28 bears out the finding of others^{24, 25} that arteriosclerosis appears at an earlier age in gouty subjects

LABORATORY DATA

Hemoglobin (Tallquist) 90 per cent Red blood cell count 4,560,000, white blood cell count 15,000 The differential leukocyte count showed 78 per cent polymorphonuclear neutrophils, 16 per cent lymphocytes and 6 per cent large mononuclear cells The maximal urine concentration observed was 1 012 The urine specimens contained neither albumin, sugar, nor diacetic acid The sediments were negative except for occasional leukocytes and hyaline casts Stool examinations were negative The Hinton test was negative A gonococcus complement fixation test was negative The sedimentation rate (Ernstene-Rourke method⁴⁷) was 0 89 to 1 3 mm per minute, 0 35 mm per minute being the upper limit of normal The serum non-protein nitrogen ranged between 20 and 27 mg per 100 cc The fasting whole blood uric acid was 5 2 to 6 5 mg per 100 cc (Folin method²⁶) for which the upper limit of normal is 5 0 A fractional intravenous phenolsulphonephthalein renal function test showed a 13 per cent excretion in the first 15 minutes, 10 per cent in the second 15-minute period and 23 per cent in the second half-hour, a total of 60 per cent This, according to Chapman's²⁷ data, indicates definite kidney impairment The bromsulphthalein liver function test was normal The blood cholesterol values were always normal Fasting gastric analysis revealed no free hydrochloric acid After histamine injection it reached 15 The arterial-venous sugar tolerance curve after the ingestion of 100 grams of glucose was as follows

| | Arterial | Venous |
|------------------------|----------|--------|
| Fasting | 96 | 97 |
| One-half hour | 166 | 153 |
| One and one-half hours | 242 | 218 |
| Three hours | 159 | 146 |
| Four hours | 100 | 97 |

No glycosuria was observed during the test

COMMENT ON LABORATORY DATA

A mild to moderate leukocytosis is always observed in patients with gouty arthritis Evidence of mild renal impairment such as found in this case is not an infrequent finding in gouty patients^{16, 25, 28} Many of them die of uremia²⁸ Therefore, one should remember the statement "chronic arthritis associated with distinct renal impairment suggests gout until proved otherwise"¹⁶ Urinary gravel and renal stones were present in 12 of 100 cases¹⁶ Achlorhydria appears to be no more frequent in gouty patients than in other individuals An abnormal peak type of sugar tolerance curve such as seen in this patient has been observed in other gouty patients as well as in patients with rheumatoid arthritis³² That this is of no diagnostic significance is shown by the fact that in other individuals with the same types of joint disease normal sugar tolerance curves are observed We have frequently observed an increased sedimentation rate in gout³² In several instances the rates have been as high as 2 0 mm per minute Such increases

are not necessarily related to alterations in the serum proteins because in several instances they have been noted in subjects having normal serum albumin and globulin values³²

SUBSEQUENT COURSE

During his hospital stay, the patient experienced numerous attacks of arthritis, varying considerably in severity (figure 1). Some were extremely mild (+), others quite disabling and extremely painful (++++) One such attack lasted two weeks, involved most of his joints and was accompanied by a temperature of 103.5° F (rectally) at times. Such attacks always responded very promptly to colchicin (grains 1/120 every 1½ hours), provided it was given until toxic symptoms (nausea, vomiting and diarrhea) appeared. Eight such tablets were usually necessary. The course of his gout and of the hyperuricemia was not materially influenced by a low purine diet over a period of three months.²⁹ The severity and frequency of his attacks while on a low purine diet did bear a relation to the urinary uric acid concentration (table 1).

TABLE I

| Showing the Relationship Between the Uric Acid Excretion and the Attacks of Arthritis | | | | |
|---|---------------------|------------------------------|--|----------|
| Date | Urine Volume c c | Uric Acid Excretion mg | Uric Acid Concentration of mg per 100 c c Urine | Symptoms |
| 1/28/35 | 1540 | 580 | 37.6 | 0 |
| 1/29/35 | 1380 | 670 | 48.5 | 0 |

| 2/20/35 | 1810 | 980 | 54.1 | 0 |

The patient was on a low purine diet during this period. We are indebted to Drs. Jacobson and Talbott of this clinic who made these determinations.

His treatment during these first two hospital stays was directed toward correction of the deformities. This was attempted by means of various types of splints and casts and operative procedures* in conjunction with exercises.

The olecranon bursa was subsequently removed (specimen I). It was filled with white, chalky material. Typical monosodium urate crystals giving a positive murexid

*The biopsies and operations were performed by Drs. F. A. Simeone, G. W. VanGorder and Sumner Roberts.

test were readily demonstrated. In order to determine with absolute certainty that the ankylosis was due to gout and not to a co-existing rheumatoid arthritis, the patient consented to a biopsy of his left ankle and foot. Biopsy specimens were removed from the ankle (specimens II and III) and the scaphoid-cuneiform joints (specimen IV). It is interesting in connection with this point that the patient's serum did give positive agglutination tests for hemolytic streptococci (Strains NY₅ and C₁₇) on several occasions. In one instance the titer was 1/1280. On other occasions, however, such agglutination tests were negative.

At a later date the patient requested amputation of the head of the proximal phalanx of the third finger in order to correct the hyperextension deformity as well as to give him a movable joint (specimen V). In order to overcome the flexion deformity of the right knee, a capsuloplasty was done. The tissue removed at the time of this operation represents specimens VI and VII. All the biopsy specimens are described in detail under pathological findings.

This patient has been under constant observation since his initial hospital entry. Studies pertaining to his hyperuricemia have been reported in this same volume (Case 2) by Jacobson.²⁹ Further detailed metabolic studies, similar to those previously reported³⁰ have been made by Dr. J. H. Talbott and will be reported in future publications.

COMMENTS ON SUBSEQUENT COURSE

Except for one serum uric acid value of 5.2 mg per 100 c.c. (following a salyrgan diuresis), this patient has always exhibited a fasting hyperuricemia of 6 or more mg per 100 c.c. of serum.²⁹ During as short a period as seven weeks, Jacobson made 33 fasting serum uric acid determinations on this patient.²⁹ These 33 values varied between 7.4 and 14.5 mg per 100 c.c. The patient received no treatment during this period. Jacobson also presents the serum uric acid variations encountered during a period when the patient was having attacks of gouty arthritis as compared with an attack-free period. In each instance the patient was on a low purine diet without other therapy. Of 13 determinations made during a period with arthritis, the fasting serum uric acid varied from 10.5 to 14.5 mg per 100 c.c. with a mean value of 12.4 ± 2.0 , whereas during the arthritis-free period, 20 determinations were found to vary from 7.4 to 13.6 with a mean value of 12.1 ± 3.0 .

Of the 177 fasting serum uric acid determinations made on 21 untreated gouty subjects Jacobson found that 174 or 98 per cent exceeded a value of 6 mg per 100 c.c. Ninety-four per cent or 167 exceeded a value of 7 mg per 100 c.c. Our experience with a larger series of gouty subjects³² on whom less frequent determinations have been made is the same, namely, that the fasting serum uric acid value of untreated gouty patients whether free of arthritis or not has always been 6 mg per 100 c.c. or over. From these data, it would appear that a hyperuricemia is practically if not always present in untreated presumptive or tophaceous gout. There may well be exceptions to this rule but if so they have not been encountered in this clinic.^{29, 30, 31, 32} Jacobson was unable to prove that the same change in the serum uric acid always preceded the attack of the arthritis. From his data it would seem that it might vary considerably from individual to individual.

and from attack to attack. In some instances it was unchanged, in others decreased or elevated. Various workers report lowering of the uric acid following treatment. It is hazardous to draw such conclusions unless the possible variations in any one subject have been well established by daily determinations over a period of seven to ten days prior to the institution of said therapy. If such control studies are not made on each patient treated, one may interpret lowering of the serum uric acid as having resulted from the treatment, whereas it may represent nothing more than the naturally occurring variations of that particular individual. Until such well controlled metabolic studies with various types of treatment have been made, we will not know the correct answer to such questions.

We are of the opinion that the requirements for uric acid determinations laid down by Talbott and Jacobson^{29, 30, 31} must be adhered to if we are to obtain comparable values giving the smallest possible variations. These are: Drawing of the fasting blood under oil, transferring it to a tube under oil, allowing it to clot, centrifuging and transferring the necessary amount of overlying serum to an Erlenmeyer flask. One can employ either the Folin³⁶ or the Benedict³⁷ method.

From table 1, it will be seen that the concentration of uric acid per 100 c.c. of urine while on a low purine diet was always greatest at the time of arthritic symptoms. A normal individual rarely excretes more than 0.6 gram per day^{24, 25}. The average daily excretion for 20 gouty patients was 0.25 gram^{24, 25}. As Pratt points out "probably 5 per cent of gouty patients have a uric acid excretion which is either a high normal or supernormal"²⁵. In this instance, a high uric acid excretion was possible even though slight renal impairment was present.

The treatment for the acute attacks of arthritis in this case has rarely been other than colchicin. This drug is practically a specific for acute gouty arthritis. It should be administered in pill form, grains 1/120 every one or two hours until nausea, vomiting, and diarrhea appear. It is then discontinued. Freedom from pain and subsidence of swelling occur within 24 to 72 hours. The diarrhea is usually sufficiently severe to require treatment with paregoric or bismuth subnitrate. Once the patient has established the amount necessary to produce such symptoms, he can reduce the total dose by 1 or 2 pills and still accomplish the desired effect. Occasionally opiates are required, though rarely if colchicin is administered as soon as the first warning symptoms appear. The patient should always carry his colchicin with him. Besides such therapy for the acute arthritis, we advise avoidance of the few high purine-containing foods and known precipitating factors, a high fluid intake and large doses of aspirin 60 to 80 grains four days out of every week. We never employ cinchophen because of the risk of inducing acute yellow atrophy and the fact that the pill form of colchicin is equally if not more efficacious. We are doubtful if this or any other regime of therapy materially affects the course of the disease. Again, one

must proceed with caution and have conditions extremely well controlled before concluding that the frequency, duration and severity of the arthritic attacks have been materially influenced. We must bear in mind the natural course of the disease, the natural interval of time between attacks and that the attack of arthritis is usually self-limited.

The necessity of employing certain medical orthopedic measures, such as some physiotherapeutic procedures, aspiration of effusions, immobilization in casts, correction of deformities by casts and operations, etc., must be borne in mind.

PATHOLOGICAL EXAMINATION

Specimen I (The olecranon bursa) It measured 2 by $1\frac{1}{2}$ by 1 cm. A soft, grayish-white, chalky material was easily expressed from freshly made sections. Microscopic examination revealed numerous, varying sized deposits of a non-cellular, lightly staining, foreign material. Under high power magnification this material was seen to consist of masses of needle shaped crystals. Many of these deposits were partially surrounded by foreign body giant cells, mononuclear leukocytes, lymphocytes, and plasma cells. Focal areas of heavy mononuclear inflammatory cell infiltration were also observed.

FIG 11 Photomicrograph of low magnification ($\times 10$) showing fibrous ankylosis of the astragalotibial joint. The cancellous bone of the astragalus is shown in the upper portion of the photograph. Small strips of eroded articular cartilage adjacent to the astragalus represent the only remaining articular cartilage. Note the numerous light areas (arrows) in the connective tissue that have replaced the joint space. These are monosodium urate crystals. They are surrounded by zones of marked chronic inflammation. Celluloidin section stained with hematoxylin and eosin.

Specimen II (Biopsy of astragalotibial joint) The specimen measured $1\frac{1}{2}$ cm in length and 7 mm in width. Near one margin of the specimen was a plate of

cartilage, representing the astragalotibial articulation. This measured 3 mm in thickness and was bounded on either side by cancellous bone. Sections from this specimen showed a large area of cancellous bone from the astragalus. The overlying articular cartilage was covered by a thick layer of dense, moderately vascular, heavily infiltrated fibrous tissue (pannus). Extremely numerous urate deposits were present throughout this layer of pannus. Most of the urate deposits were of small size. They were surrounded by a heavy infiltration of mononuclear phagocytes and foreign body giant cells. Occasional larger deposits were observed. Numerous focal areas of dense lymphoid cell infiltration were present. The intervening connective tissue was moderately heavily infiltrated with lymphocytes, mononuclear leukocytes and polymorphonuclear leukocytes.

FIG 12 A higher power photomicrograph of area outlined in the above photomicrograph. Note the invasion of articular cartilage by fibrous tissue, the areas of sodium urate deposits (arrows) and the adjacent inflammatory cell infiltration of the tissues. Magnification $\times 100$.

The underlying cartilage contained numerous small pits. These represented areas of destruction due to the invasion by the very cellular, vascular pannus tissue. In most instances such depressions contained one or more masses of urate deposits. Additional evidence of injury to the articular cartilage was exhibited by the absence or diminution in the number of cartilage cells in the more superficial areas as well as by irregularities in the matrix of the cartilage surface directly beneath the pannus. In a few areas complete destruction of the cartilage had resulted and the heavily infiltrated vascular connective tissue had penetrated the calcified zone of cartilage and extended into the subchondral bone spaces of the astragalus.

Specimen III (Biopsy of astragalotibial articulation). In this specimen, the astragalotibial joint space was replaced by a 3.5 mm band of fibrous tissue. The

entire specimen measured 1.2 by 1 cm. The histological changes observed were very similar to those seen in specimen II, except that both bones entering into the articulation were shown. These were firmly united by a dense, moderately vascular fibrous tissue (fibrous ankylosis). The subchondral bone spaces were extensively invaded by connective tissue, infiltrated with numerous inflammatory cells. The remaining cartilage consisted of small irregular fragments which were completely surrounded by fibrous tissue (pannus). Urate deposits were very numerous throughout the fibrous tissue which had replaced the joint space (figures 11 and 12).

Specimen IV (Biopsy of the scaphoid-cuneiform joint). It measured $1\frac{1}{2}$ by 0.7 cm in its greatest dimensions. It included one peripheral margin of the scaphoid and cuneiform articulation. One section through this articulation showed no abnormalities in the subchondral bone except at the extreme margin of the joint. In this region, urate deposits were observed in a few of the marrow spaces of the bone on either side of the joint. Such urate deposits were surrounded by heavy inflammatory cell infiltration including foreign body giant cells. One also noted considerable vascular fibrous tissue replacement of the bone marrow tissue wherever

FIG 13 An isolated urate deposit deep in the cancellous bone of the finger illustrated in the following photomicrograph. Examination of serial sections proved that this and other deposits of sodium urate were entirely within cancellous spaces of the subchondral bone. Celloidin section—hematoxylin and eosin stain. Magnification $\times 100$.

urates had been deposited. The overlying cartilage in these areas had been completely destroyed, suggesting that the invading urate-containing fibrous tissue had come from the joint space. However, we could not be certain because the joint capsule in this region was likewise the site of urate deposits and marked proliferation.

Elsewhere in the section the articular cartilage was thinned out and very irregular in contour. Urate deposits unaccompanied by pannus were observed on both articular

surfaces Extensive degeneration of the remaining cartilage was present as shown by the absence of many of the cartilage cells and marked fibrillation of the remaining matrix No appreciable amount of pannus was found on the remaining articular surfaces

Specimen V This consisted of the head of the proximal phalanx of the right third finger and several small fragments of the articular capsules The articular cartilage was gray and non-glistening, measuring approximately 1 mm in width Its surface was uneven because of numerous pits The head of this proximal phalanx was divided in the mid-line Serial sections were cut from each block towards the periphery of the specimen This was done in order to demonstrate whether the deposition of urates in the subchondral bone spaces was primary or the result of urate-containing pannus penetrating through the articular cartilage Because of the extensive nature of the lesions, it was impossible to answer this point with absolute certainty However, the occurrence of isolated urate deposits (figure 13), deep in the subchondral bone spaces, and the occurrence of small deposits on the surface of the articular cartilage was interpreted as strong evidence that the destructive lesions about the joints can be due to either This is what one would expect in a metabolic disease The uneven articular cartilage surface was again due to superficial urate deposits and the accompanying degeneration of the cartilage cells and matrix In addition, one noted large circular defects extending through the entire thickness of articular cartilage into the underlying subchondral bone (figure 14)

FIG 14 Photomicrograph ($\times 10$) showing the articular end of the proximal phalanx of the third left finger The free surface of the articular cartilage is frayed and uneven Cartilaginous and bony overgrowth (lipping) is present at the articular margins Two large circular defects (punched-out areas) are present in the articular cartilage and subchondral bone These lesions are lined by fibrous tissue which is infiltrated with large numbers of inflammatory cells and studded with numerous masses of sodium urate crystals Note the isolated urate deposits in the bone marrow (arrows) Celloidin section stained with hematoxylin and eosin

These defects were filled with large masses of urate crystals, which were surrounded by heavily infiltrated sheaths of connective tissue The adjacent bone trabeculae showed evidence of moderate lacunar absorption In some areas the histological

appearances suggested that following extensive undermining of the calcified zone of cartilage, collapse of the overlying articular cartilage had taken place (figure 14) Cartilaginous and bony overgrowth was present at the articular margins

Specimen VI It consisted of a piece of capsular tissue from the knee joint Microscopic examination revealed that it was studded with large and small foci of urate crystals Such urate collections were surrounded by a cellular zone containing numerous mononuclear cells having the appearance of epithelioid cells Lymphocytes, eosinophiles and occasional giant cells were also present In the areas free of urate deposits the tissues consisted of extremely dense contracted fibrous tissue

Specimen VII A small strip of articular cartilage from the posterior aspect of the femoral condyle It was greatly reduced in thickness Its surface was extremely uneven The perichondrial margin was covered by a thick layer of fibrous tissue The cartilage itself contained numerous small urate foci The irregular surface pits and depressions were covered by urate deposits The cartilage matrix was fibrillated, the cells unevenly arranged, in many regions being grouped in clumps

COMMENT ON PATHOLOGICAL EXAMINATIONS

The evidence that gout is a metabolic disease is quite convincing The fact that one can, with persistence, obtain a positive family history in a high percentage of cases is of itself extremely good evidence that it is probably an inborn disease of metabolism Further studies on the children of gouty patients will give further evidence in this direction Its occurrence in women is rare ^{3, 5, 9, 16, 24, 25} Irrespective of the various metabolic alterations observed in such patients, one fact remains, namely, that the pathological changes observed in gout are secondary to the deposition of monosodium urate Urate tophi are the only known specific lesions of gout This is true of the cutaneous, articular and visceral structures, and possibly the vascular sclerosis as well, because such sclerotic lesions are readily demonstrated in the region of urate deposits, and accompanying the heavily infiltrated vascular fibrous tissue about them The factors which govern the diffusion of urates into the various tissues are as yet unknown Once they become extravascular, they serve as foreign body irritants in consequence of which proliferation occurs We do not know the factors responsible for the more frequent deposition of urates in the articular and subcutaneous tissues It is true that visceral tophi have been observed, but many of the reported instances can hardly be considered authentic because urate crystals or a positive murexid test was not demonstrated We know of one instance of a tophus in the tongue ⁴⁰ and tophi occurring in the heart muscle have been described ^{41, 42, 43, 44 45}

In this particular case urate crystals were demonstrated in the tophi of the ear, olecranon bursa and the finger They were also observed in the cartilage, the synovial membrane, the periarticular fibrous tissue and in the subchondral bone spaces of the various joints biopsied

The articular changes encountered in gout are dependent upon the amount of monosodium urate deposited, its location and the resulting reaction to such depositions

From the observations in this case, it is apparent that articular deformity may result because of extensive fibrosis of the periarticular tissues subsequent to the urate deposition, thus producing contractures and limitation of motion

If such deposition occurs in the synovial membrane or subsynovial tissues, the resulting proliferation may be sufficiently marked to produce extensive pannus which in turn may completely cover the articular cartilages and cause a true fibrous tissue ankylosis not unlike that seen in rheumatoid arthritis. Such joints can subsequently go on to true bony ankylosis^{8, 9, 12, 14, 46}. The pannus may invade or completely destroy the articular cartilage and calcified zone of cartilage with subsequent invasion of the subchondral bone spaces with destruction of the bone trabeculae. These changes lead to the typical punched-out areas seen on the roentgenograms. The pannus in gout differs from that of rheumatoid arthritis in that one can always demonstrate islands or masses of urate crystals in the pannus, provided the tissues are placed in special fixatives. It would appear that if urate deposition occurs primarily in the subchondral spaces, the accompanying vascular infiltrated fibrous tissue proliferation may be sufficiently marked to destroy bone trabeculae and produce the same typical punched-out areas previously described.

Deposition of urates confined solely to the articular cartilage will result in marked cartilage changes such as thinning, pits, depressions, fissures, crevices, diminution in number, scattering and clumping of cartilage cells. From the observations in this case, it is apparent that urate deposition in the articular cartilage can be sufficiently injurious to explain the development of degenerative joint disease or hypertrophic arthritic changes³³ of a more advanced character than would ordinarily be encountered in an individual this age^{33, 34, 35}. Such changes were very marked in the knees of this patient (figure 8). The degenerative joint changes are in direct relation to the extent of the urate deposition and not merely an expression of long-continued use and increasing age. Therefore, we must appreciate that the deposition of monosodium urate in the articular cartilage can be responsible for the early appearance of extensive degenerative joint disease changes.

From what has been observed in this case, it must be apparent that all the described pathological changes may occur in any one joint.

Changes such as were encountered in this case have been reported previously^{6, 7, 8, 9, 10, 11, 12, 13, 14}. Virchow in 1868⁶ described a case of gout in which complete fibrous ankylosis of the phalangeal joint of the great toe took place. He stated that urate deposits were to be found not only in the cartilages, the thick layers of the periosteum, and the ligaments, but also in the fibrous tissue obliterating the joint space, within the joint itself. Isolated foci of uratic deposit were also seen in the marrow spaces of spongy bone. In 1876, Litten¹⁵ described a very severe case of gout in a patient of 41, in whom the first attack had presumably occurred at the age of eight

The hips, knees, shoulders, right elbow, wrists, fingers, and toes were all completely or partially ankylosed. In the large joints, the synovial membrane, the fibrous capsule, the ligaments, and the cartilages were all found to be covered with a thick layer of white, shiny urates having the consistency of ointment. The semilunar cartilages of the knees were almost completely destroyed. In the cartilages, the urate deposits were found exclusively in the intercellular substance, in decreasing amounts toward the epiphyseal border. The ankyloses were regarded as fibrous ankyloses with deformity and shrinking of the synovial capsule. A number of foci of urate deposits were found in the spongy bone of the epiphyses, as well as in the epiphyseal periosteum and perichondrium. In addition, urate deposits were present in the kidneys to a marked degree. The larynx was involved in the same manner. Amyloid deposit was noted in the arteries of the spleen, and amyloidosis of the kidneys was present. Although all of these changes have more recently been described in great detail in single joints by Pommer² and Brogsitter,¹⁴ it is important to appreciate that generalized ankylosis due to gout is rare.

Certain authors have reported that rheumatoid arthritis and gouty arthritis are occasionally encountered in the same individual^{38, 39}. The proof presented is anything but convincing. In all such instances, biopsies should be obtained if possible. This is the only means by which one can prove or disprove such a statement. In this case there were many aspects (particularly the physical and roentgen-ray findings) which closely resembled rheumatoid arthritis. In addition, positive streptococcal agglutination tests were obtained on a number of occasions. Some workers might consider such evidence sufficient to make a diagnosis of rheumatoid arthritis, yet biopsy of four joints demonstrated very clearly that the joint changes present were due solely to the deposition of urates in the periarticular tissue, synovial membrane, subsynovial tissue, cartilage and subchondral bone spaces. Without the biopsies, it would have been extremely difficult for us to prove that the joint deformities and ankyloses were due to gout.

This case serves to emphasize the fact that widespread ankylosis due to gout is occasionally encountered. It also illustrates another point, namely, that if one becomes gout-conscious, the incidence of gout seemingly increases. This increase, however, is directly related to one's knowledge of the disease. As it increases, so does the incidence of gout. If one is to demand the presence of tophi, characteristic roentgen-ray changes and hyperuricemia before making the diagnosis of gout, many cases of "presumptive" gout will go on for years undiagnosed or mislabelled. Our interest in this disease was aroused some years ago by the insistence of Hench that cases of "presumptive" gout are frequently not recognized. That such an assumption was correct has been borne out. Increasing suspicion of its existence has resulted in a marked increase in the number of cases so diagnosed in this clinic each year. This experience is similar to that of Hench.⁴⁸

SUMMARY

1 The findings in a severe case of gout with rapidly appearing widespread ankylosis are presented

2 Many of the clinical features resembled those seen in an individual with advanced rheumatoid arthritis

3 The diagnosis of gout in this case was confirmed by demonstrating monosodium urate crystals in the tophi of the ear, the finger and the olecranon bursa They were also demonstrated in the periarticular structures, synovial membrane, subsynovial tissue, subchondral bone spaces and articular cartilage of the four joints examined

4 The histological changes seen in the astragalotibial joint simulate those seen in advanced rheumatoid arthritis except that the pannus responsible for the complete fibrous ankylosis contained innumerable urate deposits Such urate deposits induce marked proliferation of the synovial and subsynovial tissue (pannus) Once this has formed, the ensuing changes take place rapidly

5 Urate deposits in the articular cartilage resulted in sufficient articular cartilage damage to allow marked degenerative joint changes (hypertrophic arthritis) to appear at a much earlier age than they are ordinarily encountered

6 The differential diagnosis of acute, recurrent gouty arthritis is discussed

7 The clinical features of "presumptive" gout are presented in detail with the hope that more physicians will be made gout-conscious

THE URIC ACID IN THE SERUM OF GOUTY AND OF NON-GOUTY INDIVIDUALS ITS DETER- MINATION BY FOLIN'S RECENT METHOD AND ITS SIGNIFI- CANCE IN THE DIAG- NOSIS OF GOUT¹

By BERNARD M JACOBSON, M D , *Boston, Massachusetts*

SINCE the original description by Folin and Denis¹ in 1913 of a colorimetric method for the estimation of uric acid in blood, and the application of this method in the same year by Pratt² to the study of gout, scores of publications have concerned themselves with both methods and with blood uric acid values in health and disease. To review this vast literature completely would serve no purpose, especially as many divergent results have had as their basis methods of estimation fraught with various sources of error. The present communication describes the use of the most recent Folin method in the study of a number of gouty and of non-gouty individuals. In substance the results of this study constitute an amplification and confirmation of the earlier findings of Pratt².

THE DETERMINATION OF URIC ACID IN SERUM

Since the spring of 1933 the latest Folin³ method for the determination of blood uric acid has been in use in this laboratory. In the course of the application of this method to the study of gouty patients the procedure has been adhered to with but one minor modification to be described below.

In his last paper Folin³ recommended the use of improved reagents on unlaked whole blood filtrates. He had previously⁴ proposed the use of unlaked blood filtrates in order to avoid the presence of substances which inhibit the color reaction, and of reactive, non-uric acid substances, both of which are apparently set free from laked blood cells. The unlaked blood filtrates were thought to contain the readily diffusible products of the blood cells, but were supposedly free of disintegration products of the cells. With the improvement in the sensitivity and specificity of the reagents Folin believed that the problem of the accurate determination of uric acid in small quantities of blood had been satisfactorily solved.

Early in the course of this work, on the suggestion of the late Professor

* Received for publication August 16, 1937

From the Medical Clinic, Massachusetts General Hospital, and the Department of Medicine, Harvard Medical School, Boston

A considerable part of this work was carried out during a collaborative study of gout by Dr. John H. Talbott of this clinic, and the author

Folin, we estimated the uric acid in both whole blood and in plasma of the same sample. During frequent determinations of the blood uric acid in one case of gout, it soon became apparent that the whole blood values, measured in strict accordance with Folin's directions, exhibited a degree of fluctuation far greater than the variation in simultaneously determined plasma uric acid values. The method of handling the blood has been

previously described.⁵ In brief, the venous blood, drawn without stasis from the subject under basal conditions, was treated with heparin and was then equilibrated with carbon dioxide at a tension of approximately 40 mm of mercury.* The equilibrated whole blood was then centrifuged under oil, and the plasma separated. Samples of both equilibrated whole blood and plasma were taken for analysis. Such analyses of 28 different blood samples, all from a patient suffering from gout, are given in table 1.

* The author is indebted to Dr. John H. Talbott for carrying out the equilibrations.

These data demonstrate that with increasing plasma uric acid values the concentrations of whole blood uric acid do not increase regularly. We might assume, as Folin apparently did, that the uric acid determined in unclotted whole blood represents the uric acid in the plasma together with uric acid that has diffused from the red blood cells. If this assumption be true it would be expected that the determined values of plasma and whole blood uric acid would run parallel, inasmuch as uric acid appears to be freely diffusible between plasma and cells⁶. The data of columns I and II of table 1 do not show the expected parallelism. Knowing the plasma volumes it is possible to calculate, from the value of the whole blood uric acid, the concentration of uric acid in the plasma*. Such calculations are presented in column V of table 1. It is evident that in every case but one (sample 24) the calculated *exceeds* the observed value of plasma uric acid concentration. The deviations of the calculated from the observed values are listed in column VI of table 1. It is seen that the deviations bear only a rough relation to the magnitude of the observed plasma uric acid values, the smallest being 0.63 mg per cent, and the largest 6.7 mg per cent. These deviations, which are obviously due to the extraction from the red blood cells of uric acid or of reactive, non-uric acid substances, are *variable* in magnitude, and determine the extreme variation of whole blood uric acid values among the samples with approximately equal plasma uric acid concentrations.

There appeared to be at least two possible explanations of the variable additional quantities of uric acid found in the whole blood samples. In the first place, although a sample of equilibrated whole blood was used for the determination, the handling of the specimen, fresh from the tonometer, involved rapid stirring in the atmosphere, pipetting of 1 c.c. from the sample into a 25 c.c. Erlenmeyer flask, and agitation after the addition of the sodium tungstate solution. It is obvious that this repeated exposure to the atmosphere of the sample resulted in a loss of carbon dioxide from the blood, and rendered it essentially non-equilibrated whole blood. The following experiment demonstrated the effect of the loss of carbon dioxide upon the apparent uric acid value. A sample of whole blood from a gouty individual was divided into two parts, one part stirred with heparin in an open vessel, the other part similarly treated under a layer of mineral oil. One c.c. of the latter portion was transferred under oil to the Erlenmeyer flask, and the protein was precipitated under oil. The whole blood uric acid in the portion exposed to the air measured 7.6 mg per cent, while the portion handled anaerobically yielded a value of 6.8 mg per cent. Differences in the same direction are shown by the data of table 2. In these experiments each sample of whole blood was divided into two parts, one part allowed to clot in a centrifuge tube under a layer of mineral oil, the other part in a centrifuge tube without oil, with both tubes kept at 4° C.

* Calculated plasma uric acid = whole blood uric acid X 100/plasma volume

TABLE II
Uric Acid in Serum

| Blood, Number of Sample | Serum of Blood Clotted under Oil, Uric Acid, mg per cent | Serum of Blood Clotted in Air, Uric Acid, mg per cent |
|-------------------------------|---|--|
| 1 | 10.5 | 11.0 |
| 2 | 10.3 | 10.8 |
| 3 | 10.0 | 10.6 |
| 4 | 9.7 | 10.1 |
| 5 | 7.7 | 7.7 |

for approximately $1\frac{1}{2}$ hours. It was thus evident that exposure of the blood to the atmosphere, in four of five experiments, increased the apparent uric acid content, *not only of the whole blood, but also of the serum*. On the other hand, when precautions were taken to minimize the exposure of the blood samples to the air there were obtained serum uric acid values practically identical with those of plasma of the same *equilibrated* samples. In table 3 are presented data which indicated that allowing the blood to clot

TABLE III
Comparative Uric Acid Concentration in Plasma and Serum

| Blood, Number of Sample | Plasma of Equi- librated Blood, Uric Acid, mg per cent | Serum of Blood Clotted under Oil, Uric Acid, mg per cent |
|-------------------------------|---|---|
| 1 | 12.6 | 12.0 |
| 2 | 11.6 | 11.6 |
| 3 | 11.2 | 11.4 |
| 4 | 10.5 | 10.5 |
| 5 | 10.1 | 10.2 |
| 6 | 6.7 | 6.6 |

under a layer of oil furnished serum uric acid values which closely approximated those of plasma that had been separated from the red blood cells under a physiological tension of carbon dioxide. On the basis of the fore-going data, therefore, wherever serum rather than plasma from equilibrated blood has been used, the serum has been derived from a sample of whole blood that has been allowed to clot under a layer of mineral oil. The blood was drawn into an oiled syringe, immediately thereafter the tip of the needle was inserted under the surface of a few cubic centimeters of mineral oil contained in a centrifuge tube, and the blood was then expelled under the oil. All of the uric acid values described below are based upon analyses of such sera, or of plasma of equilibrated blood.

That this apparent increase in uric acid content accompanying the slight loss of carbon dioxide depends upon a migration of uric acid or of reactive, non-uric acid substances, from the blood cells into the serum as the blood becomes more alkaline is suggested by the experimental data of Jacoby and

Friedel⁷ These authors studied the loss of uric acid from the plasma after the addition of known amounts of uric acid to whole blood maintained by phosphate buffers at pH 7.38, 7.17, and 6.46, respectively. In every one of 13 such experiments an increase in the pH was accompanied by greater recovery in the plasma of the added uric acid. A shift in the same direction of both native and of added uric acid has more recently been reported from this clinic by Talbott and Sherman⁶

A second explanation of the variable increments of whole blood uric acid, over the calculated values of plasma content, was the possibility that the reagents used in precipitating the unlaked blood cells might extract from the cells uric acid, or reactive non-uric acid substances. This possibility has been rendered probable by the work of Heller⁸. He showed that *variable* amounts of uric acid (or of chromogenic material) could be washed out of the blood cells by the hypertonic sodium tungstate solution, and that additional but *inconstant* amounts were extracted during acidification with the sulfuric acid. The averages of a number of determinations were 1.32 mg per cent extracted by the sodium tungstate alone, and 1.85 mg per cent after the addition of the sulfuric acid. This latter value is of the same order of magnitude as the average of the present experiments (column VI, table 1).

Because of these variable degrees of extraction from the blood cells, it seemed desirable to give up whole blood uric acid determinations entirely, and to determine uric acid only in serum in the manner described above. Plasma or serum uric acid determinations have been employed in the past by many investigators, including Folin, Berglund, and Derick,⁹ Thannhauser,¹⁰ and Wiener and Wiener.¹¹

THE RECOVERY OF ADDED URIC ACID

Two procedures have been commonly employed in the past to define the specificity and the accuracy of various methods for the determination of uric acid in blood, namely, a comparison between the results of colorimetry directly upon the blood filtrate with the values obtained after preliminary precipitation of the uric acid, and the extent of recovery of uric acid added to blood. That all of the color developed by the Folin 1933 reagents is probably due to uric acid is suggested by the fact that both the direct and the indirect methods yield practically identical values. In his last paper³ Folin demonstrated that applying the reagents directly to the unlaked whole blood filtrates resulted in values no higher than those obtained after preliminary precipitation with silver nitrate. For this reason all of the values reported below represent *direct* determinations on the serum filtrate.

Throughout the literature concerning the determination of uric acid there have repeatedly cropped up reports of incomplete recoveries of uric acid added to whole blood.¹² The earlier claim of quantitative recoveries made by Folin and Wu¹³ was within three years corrected by Folin,¹⁴ who then admitted that losses of as much as 10 per cent of added uric acid might

be encountered. It was principally because of this incomplete recovery that Folin in 1930⁴ turned to the use of *unlaked* whole blood filtrates, and demonstrated that the loss of added uric acid was not dependent solely upon adsorption of uric acid by the precipitated protein, but rather was due to the fact that something in laked blood filtrates *depressed* the color reaction. This inhibitory effect was apparently completely avoided when unlaked blood filtrates were used, as evidenced by the quantitative recoveries of uric acid added to such bloods⁴. Similarly, data presented by Folin in his last paper³ showed that of uric acid added to whole blood from 94 to 100 per cent was recovered. On the other hand, data are not lacking which indicate substantial losses of uric acid added not to whole blood but to *plasma*. Thus Wiener and Wiener,¹¹ using the Folin 1922 reagents, found the following recoveries of small amounts of uric acid added to plasma: 72, 83, 95, 77, and 100 per cent respectively. Similarly, in the hands of the author the application of the Folin 1933 method to plasma or to serum has not consistently yielded quantitative recoveries of added uric acid. In table 4 are

TABLE IV
Recoveries of Uric Acid Added to Plasma or Serum

| Experiment Number | Uric Acid Added, mg per cent | Uric Acid Recovered, per cent of uric acid added |
|-------------------|------------------------------|--|
| 1 | 3.33 | 96 |
| 2 | 4.00 | 61 |

| 29 | | 99 |
| 30 | | 102 |
| Average | | 90 |

presented the results of 29 experiments. With the exception of one experiment the recoveries were 80 per cent or better, and in 16 experiments the recoveries exceeded 90 per cent. The recoveries could not be consistently bettered by the addition of the uric acid dissolved in the sodium tungstate solution, or by the delivery of the sulfuric acid at an extremely slow rate, with constant stirring of the precipitation mixture. On the other hand, that much of the loss is due to the adsorption of added uric acid by the *precipitated* protein is shown by the following recoveries, after the addition of 10 mg per cent of uric acid *subsequent* to the precipitation of the protein: 96, 89, 99, 98, and 93 per cent, respectively. It must be concluded, therefore, that the present method for the determination of uric acid in serum may involve negative errors of an average magnitude of 10 per cent.

THE SERUM URIC ACID IN NON-GOUTY INDIVIDUALS

The serum uric acid was determined, under basal conditions, in 100 non-gouty adults. All of the subjects had been consuming a mixed diet. In most instances one such value was obtained for each individual, where more than one determination was performed the highest value has been recorded. Among 37 females the mean age was 39.2 years, and among 63 males the mean age was 44.5 years. Of the 100 subjects only 24 were considered free of organic disease. The remaining 76 subjects were hospital and private patients suffering from a variety of, for the most part, chronic diseases. In the choice of these non-gouty patients for the present study there were excluded only those suffering from renal disease with nitrogen retention, disease of the liver, and leukemia, conditions in which it is well established that abnormally high uric acid concentrations may be encountered.

In table 5 are presented the frequency distribution of the non-gouty

TABLE V
Frequency Distribution of Serum Uric Acid Values in 100 Non-Gouty Individuals

| Serum Uric Acid, mg per cent | 10-19 | 20-29 | 30-39 | 40-49 | 50-59 | 60-69 |
|---------------------------------|-------|-------|-------|-------|-------|-------|
| 63 Males | 0 | 8 | 13 | 23 | 16 | 3 |
| 37 Females | 1 | 6 | 7 | 16 | 7 | 0 |
| 100 Total | 1 | 14 | 20 | 39 | 23 | 3 |

values of serum uric acid concentration. It is seen that the distribution of values among the males and the females is very similar, in each case at a maximum between 40 and 49 mg per cent. The mean serum uric acid content among the males was 4.4 ± 0.09 , among the females 4.0 ± 0.11 , and among the entire 100 non-gouty individuals 4.2 ± 0.07 mg per cent, respectively.

Included in the data of table 5 are values from two patients who had passed uric acid vesical calculi, but without evidence of gout. The serum uric acid content in one case was 4.5 mg per cent, and in the other case was 3.6 mg per cent.

The Serum Uric Acid in Non-Gouty Arthritis Twenty cases of non-gouty joint disease are included in the cases described above. The diagnosis in most of the 20 cases was arrived at only after exhaustive study. The serum uric acid values found in these cases are presented in table 6. It

TABLE VI
The Serum Uric Acid in Non-Gouty Arthritis

| Diagnosis | Case Number | Serum Uric Acid, mg per cent |
|---|-------------|------------------------------|
| Rheumatoid Arthritis | 1 | 2.4 |
| " " | 2 | 2.6 |
| " " | 3 | 2.9 |
| " " | 4 | 3.2 |
| " " | 5 | 3.3 |
| " " | 6 | 3.3 |
| " " | 7 | 3.5 |
| " " | 8 | 3.7 |
| " " | 9 | 4.3 |
| " " | 10 | 5.0 |
| " " | 11 | 5.6 |
| " " | 12 | 5.7 |
| " " | 13 | 5.9 |
| " " | 14 | 6.7 |
| Hypertrophic Arthritis | 15 | 4.2 |
| " " | 16 | 4.7 |
| " " | 17 | 4.9 |
| Gonorrheal Arthritis | 18 | 5.2 |
| Multiple Foci of Osteomyelitis | 19 | 6.2 |
| Arthritis or Periostitis, cause unknown | 20 | 6.7 |

is to be noted that the only cases among all of the non-gouty individuals in whom serum uric acid values in excess of 6.0 mg per cent were found include three listed in table 6 (cases 14, 19, and 20). All were males, none showed any clinical evidence of gout, and in none was there evidence of impaired renal function or of hepatic disease. Case 14 suffered from spondylitis deformans (rheumatoid arthritis), case 19 was one of multiple foci of osteomyelitis, and case 20 was diagnosed arthritis or periostitis, cause unknown.

Similar *infrequent* instances of elevated blood uric acid values in chronic, non-gouty arthritis have been reported by Pratt.¹⁵

The mean serum uric acid among the 20 cases of non-gouty arthritis was 4.6 ± 0.20 mg per cent. This value exceeds the mean of the entire 100 non-gouty individuals by only 0.4 ± 0.21 mg per cent, a difference of no statistical significance.

THE SERUM URIC ACID IN GOUT

Material The material of the present study consisted of 21 cases of gout. In nine cases the characteristic sodium urate crystals yielding a positive murexide test were obtained from tophi. In the remaining 12 cases

demonstrable or accessible tophi were not present. In these cases the diagnosis was based upon a characteristic history and physical finding, and was agreed upon by several observers. Both clinical and metabolic descriptions of cases 1 and 3 have been previously published⁵, case 2 forms the subject of a contemporary study¹⁶. Data on case 11 were reported in 1926 by Folin, Berglund, and Derick⁹.

In table 7 are presented all relevant data concerning the gouty subjects. All were males, with the exception of case 3. The ages of the patients ranged between 21 and 73 years. The duration of the disease varied from 4 months to 36 years. In ten cases chronicity of the disease was evidenced by deformities of joints or by characteristic roentgenologic bony lesions. In only seven patients was chronic gouty arthritis present (cases 1, 2, 3, 4, 11, 17, and 18). In the remaining 14 cases recurrent attacks of acute gouty arthritis had left no joint defects. All types of severity of gout were represented by these cases, ranging from case 2, of chronic gouty arthritis with multiple extensive ankyloses, and with superimposed attacks of acute gouty arthritis at intervals of a few weeks, to case 14, free of chronic changes and free of gouty attacks since the initial one three years previously.

In six cases there was present some degree of renal insufficiency, which by itself partially invalidates the diagnostic significance of the elevated uric acid values. The evidence for renal insufficiency was furnished principally by the non-protein nitrogen content of the blood and by the excretion of intravenously injected phenolsulphonephthalein, and in some cases by the urinary specific gravity during a concentration test. The values of non-protein nitrogen content in table 7 are to be interpreted in terms of the normal range of 20 to 35 mg per cent in whole blood, and of 20 to 30 mg per cent in serum. The excretion of phenolsulphonephthalein 15 minutes after the intravenous injection of 6 milligrams of the dye amounts to at least 25 per cent in normal individuals¹⁷. On the basis of these tests case 3 was considered one of moderate renal insufficiency, while cases 2, 11, 16, 17, and 18 represented minimal degrees of renal impairment.

Disease of the liver occurred in only one instance, case 17, in which acute yellow atrophy was present, accompanied by marked disturbance of hepatic function.

Among the 21 cases of gout the serum uric acid was determined on a total of 177 occasions, under various conditions to be described in detail below. On 174 occasions (98 per cent of total) the serum uric acid content exceeded 6.0 mg per cent, on 167 occasions (94 per cent of total) the value exceeded 7.0 mg per cent. Four values ranged between 14.1 and 14.8 mg per cent.

The Influence of a Purine-Free Diet Upon the Serum Uric Acid Level
That the consumption of a purine-free diet over a prolonged period is often followed by a slight depression of the blood uric acid level in gouty individuals has been reported by many investigators. The present data are

necessarily limited by the fact that the few subjects who consumed a purine-free diet did so for *relatively short periods*. Thus the longest such period, during which the serum uric acid was determined frequently, was three months (case 1). Moreover, there are lacking for comparison sufficient data on the same subject obtained while on a mixed diet. All of the data are depicted in table 7 in relation to other possible influences on the serum uric acid level. In no single case were there gathered sufficient values to permit a statistical comparison of the effect of variation only in the diet with all other influences equal. The few individual values of serum uric acid content while a purine-free diet was consumed *appear* to be slightly lower than those obtained while the subjects consumed a mixed diet (cases 1 and 3). On the other hand, it is evident that a purine-free diet, consumed over short periods, did not result in a fall of the serum uric acid content to a non-gouty level. Thus, of a total of 61 determinations among five patients (cases 2, 3, 4, and 8), free of acute gout and maintained on a purine-free diet without specific medication, only one value was as low as 6.0 mg per cent, while 55 values exceeded 7.0 mg per cent. Under similar restrictions of diet and of medication 51 values were obtained among six patients during attacks of acute gout. None of these values fell below 7.0 mg per cent.

The Influence of Various Drugs Upon the Serum Uric Acid Level In many instances the serum uric acid was determined while the patients were under the influence of one or more of several drugs which have been found, by many observers, to often lower the blood uric acid level. These drugs are aspirin, colchicin, and salyrgan. None of the subjects of the present study were under the influence of cinchophen or of related materials.

It may be seen in table 7 that only scanty data were obtained in any one patient while medication was administered, and *while a purine-free diet was consumed*, either during an interval between attacks of acute gout or during an attack. In case 1 on a purine-free diet and during several gouty attacks a total of 29 determinations of serum uric acid were performed while drugs were withheld, the mean of these values was 10.7 ± 0.17 mg per cent. While drugs were administered (aspirin, as much as 4 grams daily for several days, or colchicin, as much as 8 milligrams on any one day) 8 determinations of serum uric acid yielded a mean of 10.4 ± 0.38 mg per cent.

In a few instances drugs were apparently responsible for significant changes in the serum uric acid content. On one occasion the administration to case 1 of 3.0 milligrams of colchicin was followed by an apparent temporary fall of the uric acid to 8.5 mg per cent (depicted in figure 1, February 6, 1934), which succeeded a marked urinary excretion, on February 5, of 1.42 grams of uric acid. It is, of course, possible that this temporary fall was a result of some influence other than the colchicin. One of the lowest serum uric acid values among the entire 177 values was found in case 9 (table 7). During the nine days prior to the first determination (October

1, 1935) the left olecranon bursa was involved in an acute attack of gouty arthritis, by October 1 the active pain was absent, but pain on motion and moderate swelling and tenderness of the elbow were still present. During the previous five days the patient had consumed 2.6 grams of aspirin daily. The serum uric acid on October 1 was 5.7 mg per cent. Medication was withheld. The following day the serum uric acid was 8.2 mg per cent. That this low value of 5.7 mg per cent was related to the administration of the aspirin rather than to other influences is rendered likely by further data to be presented below.

FIG 1 *Case 1* Serum uric acid levels in relation to acute attacks of gout and to administration of colchicin (Purine-free diet, constant fluid intake of 2000 c.c. daily)

In four experiments among three patients the intravenous administration of salyrgan was followed by a significant temporary fall of the serum uric acid. Two of these experiments are depicted in figure 2, and a third in figure 3. In the latter instance the serum uric acid fell to 5.2 mg per cent, the lowest value among the entire 177 determinations. In a fourth experiment on case 1 a serum uric acid level of 11.9 mg per cent was succeeded, on the day after the intravenous injection of 2 c.c. of salyrgan, by a value of 8.1 mg per cent. In all of the above experiments the lowering of the serum uric acid levels followed a markedly increased urinary excretion of uric acid.

The Relationship of the Serum Uric Acid Level to the Attack of Acute Gouty Arthritis The possible relationship of the blood uric acid level to the attack of acute gouty arthritis has been studied by many observers, with almost as many divergent results as a consequence. That the blood uric acid rises just before an attack is a view shared by Lichtwitz and Stemitz,¹⁸ Lucke,¹⁹ and by Chrometzka.²⁰ That no such pre-attack rise occurs was stated by Gudzent.²¹ Pratt,¹⁵ writing in 1921, thought that the blood during

an acute attack usually contains slightly more uric acid than at other times Rathery and Violle²² and Thannhauser¹⁰ held that the uric acid falls during an attack Finally, Richter²³ maintained that the blood uric acid at the beginning of an attack is *either* elevated or depressed

FIG 2 Case 2 Serum uric acid levels in relation to administration of salyrgan and to acute attack of gout (Purine-free diet, constant fluid intake of 2000 c c daily) On each day denoted by an arrow 1 c c of salyrgan was injected intravenously, after blood was drawn for analysis

In the opinion of the present writer, none of the above generalizations are based upon sufficient experimental evidence It is apparent that critical evidence must include very frequent observations of blood uric acid throughout an interval between acute attacks and during the attack of acute gouty arthritis, under controlled conditions of diet and of medication The present data constitute only an approximation to this ideal In figure 2 are depicted frequent observations of the serum uric acid in case 2 over a period of 29 days It is evident that prior to the administration of salyrgan on March 4, during an asymptomatic interval, the serum uric acid *fluctuated* considerably, and that similar *fluctuation* took place during the twelve days of the attack of acute gout (Any possible change of the uric acid level

just prior to the attack was, of course, masked by the effect of the salyrgan administered on March 11) Quantitatively much less marked variations were found in case 3, depicted in figure 4 These observations have been

FIG 3 Case 4 Serum uric acid levels in relation to administration of colchicin and salyrgan (Purine-free diet, constant fluid intake of 2000 cc daily) On each day denoted by an arrow 1 cc of salyrgan was injected intravenously after blood was drawn for analysis

included in a previous report⁵ It is evident that the slight fall in the serum uric acid between April 6 and 10 might have been due to the change from a mixed diet to a purine-free diet on April 6, rather than related to the first attack of acute gout During the following asymptomatic interval prior to the second attack of acute gouty arthritis the serum uric acid *apparently* declined, and then *apparently* rose during the first two days of the attack More extended observations were made in case 1 and are presented in figure 1 (The data of December 7 to 21 have been included in a previous study⁵) In this case it is evident that the serum uric acid values, other than those possibly related to the administration of colchicin, showed a high degree of fluctuation and bore no consistent relation to the acute attacks Any apparent change just prior to or during the attacks was matched by equally apparent changes during the asymptomatic intervals

It seems to the writer that the data described above illustrate the futility

of seeking evidence of a change among the highly variable successive serum uric acid values by mere *inspection* of the uric acid curves. It was on the basis of such observations that the several different generalizations in the

FIG 4 Case 3 Serum uric acid levels in relation to acute attacks of gout (Purine-free diet, constant fluid intake of 2000 c c daily)

literature were founded. Rather, the inherent variability of serum uric acid values requires the statistical treatment of a large number of such values. In two gouty subjects sufficient data were collected to justify a statistical analysis. All of the data on case 2, obtained while the patient consumed a purine-free diet and while medication was withheld, are included in table 7. It is seen that the mean of a total of 20 serum uric acid values collected during all parts of asymptomatic intervals was 12.4 ± 0.20 mg per cent, while the mean of 13 values measured during all parts of acute attacks of gouty arthritis was 12.1 ± 0.31 mg per cent. Similar but more extended observations were made in case 1. In table 7 are presented all of the serum uric acid values obtained while the patient consumed a purine-free diet without medication, in relation to 18 attacks of acute gouty arthritis over a period of one year.

It is seen that the mean of 25 serum uric acid values during asymptomatic intervals was 11.0 ± 0.18 mg per cent, while a practically identical mean of 10.7 ± 0.17 mg per cent was found among 29 determinations during acute attacks. Thus, when all phases of asymptomatic intervals were compared with all phases of acute attacks of gout in these two cases, no change

of the serum uric acid was observed. On the other hand, a more detailed analysis of the data in case 1 yielded a different interpretation. In table 8 are presented the serum uric acid values in relation to finer sub-divisions of

TABLE VIII
Serum Uric Acid Levels in Several Phases of Acute Attacks of Gouty Arthritis
Case 1 Purine-free diet, no medication

| | Intervals | | Acute Attacks of Gouty Arthritis | |
|-------------------------------------|---------------------------------------|---------------------------------|----------------------------------|----------------------------|
| | Earlier than 3 Days Preceding Attacks | Within 3 Days Preceding Attacks | First 2 Days | Subsequent to First 2 Days |
| Number of determinations | 12 | 13 | 12 | 17 |
| Range, serum uric acid, mg per cent | 10.5-13.3 | 9.1-13.7 | 9.7-13.4 | 8.3-13.5 |
| Mean, serum uric acid, mg per cent | 11.7 \pm 0.18 | 10.3 \pm 0.25 | 10.6 \pm 0.22 | 10.8 \pm 0.24 |

the intervals and of the periods of acute gouty arthritis. It is evident that *during the three days prior to the acute attacks the serum uric acid fell* from a previous mean of 11.7 ± 0.18 mg per cent to one of 10.3 ± 0.25 mg per cent, a significant difference of 1.4 ± 0.31 mg per cent. The additional data of table 8 demonstrate that *during the gouty attack the serum uric acid remained unchanged*.

The Serum Uric Acid Level in Relation to the Severity of Gout. In only four of the present 21 cases of gout were there obtained a sufficiently large number of serum uric acid values, under comparable conditions of diet and of medication, to justify an attempt to correlate the height of the uric acid level with the severity of the disease. On the basis of frequency and severity of attacks, and the extent of chronic joint deformities, it was considered by several observers that the four cases, in the order of their severity, were cases 2, 1, 3, and 4. In table 7 it is seen that during asymptomatic intervals (purine-free diet, no medication) the means of the serum uric acid values of these cases were 12.4 ± 0.20 , 11.0 ± 0.18 , 8.6 , and 6.9 ± 0.08 mg per cent, respectively. During attacks of acute gouty arthritis (purine-free diet, no medication) the means were 12.1 ± 0.31 , 10.7 ± 0.17 , and 8.8 ± 0.06 mg per cent, respectively. (Data are lacking in case 4 in this category.) These respective differences in mean values are statistically significant. These data suggest, therefore, that in these four cases a more severe degree of gout was accompanied by a higher level of the serum uric acid.

Among the remaining 17 cases the serum uric acid values were insufficient in number to adequately characterize the uric acid level of any one case. However, the heights of the individual serum uric acid values did not appear related to such clinical aspects as the presence or absence of

chronic gouty arthritis or of tophi, the duration of the disease, or the frequency of attacks of acute gouty arthritis. With the exception of one of two values in case 9 (*vide supra*), the serum uric acid in every gouty individual was elevated.

The Serum Uric Acid Level Among Close Relatives of Gouty Individuals As early as 1916 Folin and Denis²¹ reported "a normal man of a gouty family" with an elevated whole blood uric acid (40 mg per cent). As far as the present writer is aware, similar additional studies have not been published in the vast literature concerning gout and uric acid in the blood. Although a systematic investigation of the uric acid metabolism of close relatives of gouty individuals has not been carried out, the following observations require mention. The serum uric acid was determined in three individuals, all adult males and completely free of a history or physical signs of joint disease. In all the non-protein nitrogen content of the blood was normal. The following serum uric acid values were found: a son of case 4, 67 mg per cent,* a son of case 6, 77 mg per cent, and a brother of case 5, 84 mg per cent, respectively.

The Significance of the Serum Uric Acid Level in the Diagnosis of Gout It is evident from the foregoing presentation that in only a few instances among the 177 determinations of the serum uric acid in 21 cases of gout, under various conditions, were the values within the range established in the 100 non-gouty subjects. Thus in case 4 (see figure 3 and table 7), among 14 determinations performed over a period of one month, one value of 52 mg per cent followed the administration of salyrgan on the previous day, three other values, unrelated to medication, were 60, 66, and 67 mg per cent, respectively, while the remaining 10 values ranged between 69 and 74 mg per cent. In case 9 the value of 57 mg per cent was found at the end of a five-day period in which 26 grams of aspirin were consumed daily, a second determination yielded a value of 82 mg per cent. Of the total 177 values, therefore, 175 values ranged between 60 and 148 mg per cent. In contrast, 97 of 100 determinations among 100 non-gouty individuals yielded serum uric acid values less than 60 mg per cent, three of the 100 values ranged between 60 and 67 mg per cent.

The high serum uric acid values found in three relatives of gouty individuals have been described above. This finding must obviously be brought to bear upon the interpretation of an elevated uric acid level in the absence of gout, renal insufficiency, disease of the liver, or leukemia.

Comparable with the present serum uric acid values in gout are the plasma uric acid levels ranging between 65 and 107 mg per cent, found in 11 determinations among nine gouty individuals by Folin, Berglund, and Derick.⁹

As far as the author is aware, the only other series of determinations, among gouty individuals, approaching the high proportion of elevated uric acid values of the present study is that of Jordan and Gaston²⁵. These

* This individual was studied in collaboration with Dr. John H. Talbott.

workers used the Folin 1930 method on unlaked whole blood. The upper limit of normal they took as 4.0 mg per cent. In 53 determinations among 17 cases of gout the whole blood uric acid exceeded 4.0 mg per cent in 47 instances.

The modern literature concerning the blood uric acid in gout, on the basis of older analytical methods, ranges between the view expressed by Thannhauser¹⁰ that an elevated value is a constant finding in gout, to the observations by Gudzent²⁶ of *normal whole blood uric acid values in one-third* of 26 cases of gout. Similar to the latter findings were the observations reported in 1928 by Hench, Vanzant, and Nomland²⁷. Among 100 cases of gout these authors found *normal whole blood uric acid levels in 28 cases*. Writing as late as 1936 Hench²⁸ found that *the whole blood uric acid was constantly elevated only in untreated chronic gouty arthritis*.

As far as the writer is aware, the present 177 determinations of the serum uric acid among 21 cases of gout, representing all types of the disease, under a variety of conditions, constitute the most extensive study of the problem of uricemia in gout. The results of this work amply confirm the original observations by Pratt² in 1913, based upon the use of the forerunner of modern colorimetric analytical methods, that hyperuricemia is practically constant in untreated gout. With the present method of estimation hyperuricemia is defined as a serum uric acid content in excess of 6.0 mg per cent.

SUMMARY

The determination of uric acid in blood by means of the Folin 1933 method yielded experimental evidence for the view that analysis of *serum*, derived from blood allowed to clot under oil, furnishes more valid data than does *whole blood*.

The fasting uric acid in 100 non-gouty individuals consuming a mixed diet ranged from 1.9 to 6.7 mg per cent, with a mean of 4.2 ± 0.07 mg per cent. In 97 individuals the serum uric acid was less than 6.0 mg per cent.

The serum uric acid was determined on 177 occasions in 21 cases of gout, under various conditions. The serum uric acid values ranged from 5.2 to 14.8 mg per cent. On 174 occasions (98 per cent of total) the value exceeded 6.0 mg per cent, on 167 occasions (94 per cent of total) the value exceeded 7.0 mg per cent.

The consumption by gouty individuals of a purine-free diet during periods shorter than three months did not significantly influence the serum uric acid level. The administration of aspirin, colchicin, and salyrgan to gouty individuals on several occasions was followed by an apparent temporary fall of the serum uric acid level.

The serum uric acid frequently determined in four gouty individuals, apparently exhibited marked fluctuation both during asymptomatic intervals and during attacks of acute gouty arthritis. An intensive study of one case

of gout over a period of one year demonstrated a significant fall of the mean serum uric acid level during a three-day period preceding attacks of acute gouty arthritis, during the attacks the serum uric acid level remained unchanged

Among four cases of gout an apparent direct correlation was found between the height of the serum uric acid level and the severity of the disease

The serum uric acid was determined in the son of each of two gouty individuals, and in the brother of a third gouty individual. These relatives themselves were free of gout. Their serum uric acid concentrations were 6.7, 7.7, and 8.4 mg per cent, respectively

The author is indebted to Drs. Walter Bauer, Arlie V. Bock, and Saul Hertz of this clinic for permitting observations on patients from their private practice. Dr. Walter Bauer, and Dr. Harry C. Trimble of the Department of Biological Chemistry, Harvard Medical School, have made many helpful suggestions during the course of the work and in the preparation of the manuscript.

"PLATE-LIKE" ATELECTASIS OF THE LUNG

By ALICE ETTINGER, M D , *Boston, Massachusetts*

THE clinical importance of atelectatic conditions of the lung and their proper roentgenological recognition has recently been emphasized. Attention has been called to the frequent occurrence of atelectasis in tuberculosis,¹ in bronchiectasis,^{2, 3, 4} in minor upper respiratory infections.⁵ Usually the collapse of a whole lobe or nearly a whole lobe has been described. The so-called basal triangular shadow as evidence of lower lobe collapse, the triangular shadow at the apex in atelectasis of the upper lobe, as well as the appearance of the collapsed middle lobe have been described in detail by numerous writers.^{6, 7, 8, 9, 10} In addition to the characteristic form of the dense shadow cast by the collapsed lobe, the presence of a mediastinal shift is generally considered to be a valuable sign in the differential diagnosis of atelectasis.¹¹ In partial collapse, the mediastinal shift may be completely absent, but the displacement of the interlobar septum towards the diseased lobe is helpful in making a diagnosis.^{10, 12} The smallest localized areas of atelectasis which occur, due to obstruction of a bronchus of the second or third division, do not, however, produce any shift of the interlobar septum. The term generally used to describe small atelectatic areas is that of "patchy atelectasis." Patchy atelectasis is supposed to be indistinguishable from bronchopneumonic infiltration.¹³

Recently, Fleischner¹² has convincingly shown that small areas of pure atelectasis without complicating secondary changes of the parenchyma, are represented by "plate-like" shadows in the lung, which appear as horizontal stripes in both postero-anterior and lateral views. Previously, such horizontal stripes frequently have been mistaken for fibrinous deposits on the pleura.¹⁴ Fleischner observed these stripes associated with three groups of conditions

1 Abdominal diseases

In this first group of diseases the horizontal shadow stripes had been observed by other authors previously to Fleischner,^{14, 15, 16} and had been interpreted as being due to pleurisy.

2 After contusions of the chest

3 Associated with minor upper respiratory infections

Fleischner, by autopsy controls, demonstrated that these plate-like shadows were due to small atelectatic areas. It seemed to us that a further

* Received for publication August 16, 1937

From the Department of Radiology, The Boston Dispensary

proof could be offered by observing the development of these shadows during the reexpansion of a lobar infectious atelectasis. In infectious atelectasis a previously normal lobe collapses and often reexpands before severe

FIG 1 P A view Dec 24, 1935 Triangular shadow at the base of the right lung field merging with the shadow of the heart and the right diaphragm Typical appearance of collapse of the right lower lobe

chronic changes, such as bronchiectasis or fibrosis, develop^{5 17} It has been shown that the collapse in these cases is not to be explained by a gross plugging of a main bronchus, but by the presence of tenacious sputum in numerous smaller sized bronchi. During the stage of reexpansion, a few smaller-sized bronchi may remain plugged longer than others. The small atelectatic pulmonary areas supplied by these bronchi should be demon-

strable at this stage as horizontal shadow stripes. We have seen that this occurs. In a number of cases of typical acute lobar collapse in children due to upper respiratory infection, the horizontal shadow stripes appeared on the

FIG 1a Lateral view Dec 24, 1935 Note collapsed right lower lobe as a dense shadow overlying the spine

roentgen-ray film during the stage of re-inflation. They represented at this time the only abnormal finding. Clinically, the health of the patient seemed to be fully restored. The following case may be reported as an example.

CASE REPORT

Case 1 (I am indebted to the Boston Floating Hospital for the case history.) W. H., a nine year old boy, was admitted to the Boston Floating Hospital on

December 23, 1935, because of fever and anorexia of 10 days' duration. He had suffered from measles at the age of six, and whooping cough at four. Since the whooping cough the boy had frequent attacks of cough and fever during the winter.

On admission, there was rapid breathing and cough. The examination showed

FIG 2 P A view Oct 5, 1936 Collapse of the right and the left lower lobes

limitation of expansion on the right side and dullness posteriorly from apex to base. The breath sounds were diminished and expiration prolonged over this area. The temperature was 101° on admission and terminated by crisis one day later. It stayed normal thereafter.

Films taken one day after admission showed a typical triangular shadow at the right base indicating total collapse of the right lower lobe. There was also some mottling in the left lower lung field behind the heart (figures 1 and 1a).

The patient gradually improved and was discharged on January 16, 1936, to

a recreation home. Roentgen-ray examinations were not repeated at the time of discharge. It was intended to introduce lipiodol into the right lower lobe at a later date, to determine whether or not bronchiectases were present. This seemed advisable because of the present conception that bronchiectasis may develop in cases of spontaneous lobar atelectasis^{18, 4, 7, 5}

FIG 3 P A view Nov 2, 1936. The right lower lobe has partially reexpanded. Indefinite cloudiness in the right cardio-diaphragmatic angle. Arrows indicate the displaced interlobar septum.

In March 1936, three months later, chest films were again taken and showed the right lung to be entirely normal. The previously collapsed right lower lobe had completely reexpanded.

On September 27, 1936, nine months after the original episode, the patient was re-admitted to the Boston Floating Hospital because of fever, cough, shortness of

breath, and pain in the region of the right lower chest of one week's duration. In the interval between March and September, the boy had been well, with the exception of one week's sickness in June, with similar symptoms.

On admission the boy appeared acutely ill, dyspneic, coughing, raising a considerable amount of sputum. Physical findings showed impaired resonance at both bases,

FIG 4 P A view Nov 30, 1936 Arrows indicate a horizontal shadow stripe in the right lower lobe, which represents "plate-like" atelectasis

with diminished breath sounds at the left base. No râles were heard. Tactile fremitus was slightly more pronounced on the right side. The temperature was 103° on admission and dropped to normal at the end of 12 days. Films taken one week after admission (October 5, 1936), while the patient was still acutely ill, showed

collapse of the right and left lower lobes (figure 2) Reexamination on November 2, 1936, showed marked improvement There was now partial collapse of the right lower lobe only (figure 3) Clinically, the child had markedly improved in the meantime The temperature was normal The cough had disappeared On November

FIG 4a Right oblique view Nov 30, 1936 Arrows indicate the "plate-like" atelectases In this view an atelectatic area in the left lower lobe has become visible, which in the P A view was hidden behind the heart shadow

30, 1935, the child appeared clinically well Films taken at this time showed both diaphragms smooth in outline, freely movable with respiration There were two transverse shadow stripes in the right lower lung field and one in the left lower lung field

Interpretation These shadow stripes were considered to represent minute

atelectases due to occlusion of small-sized bronchi in the right and left lower lobes (figures 4 and 4a)

In differential diagnosis, pleural adhesions alone have to be considered. The appearance of the atelectatic areas as thin stripes in both the anterior and lateral films makes it obvious that we are dealing with a plate-like and not with a linear structure. The intrapulmonary origin is therefore evident.

Fleischner explains the appearance of these plate-like shadows by a mechanism which he calls "directed collapse." While in pneumothorax the lung can retract from the lateral chest wall due to the change of pressure within the chest cavity, the conditions for collapse in obstructive atelectasis are fundamentally different. Here, the lung cannot retract from the chest wall. Even if no pleural adhesions are present, the negative pressure acts as an adherent force between the surface of the lung and the chest wall and prevents the collapse of the lung toward the hilus. As there is no possibility for the lung to shrink in a costo-mediastinal direction as in pneumothorax, the tendency of the atelectatic area to diminish in extent can only take place in a crano-caudal direction, perpendicular to the axis of shrinkage in pneumothorax.

CONCLUSION

A case of acute lobar collapse due to upper respiratory infection is reported. In the end stage of reexpansion, thin horizontal shadow stripes were seen in the area previously collapsed, and were interpreted as "plate-like" minute areas of atelectases.

A COMPARISON OF THE PRESSURES IN ARM VEINS AND FEMORAL VEINS WITH SPECIAL REFERENCE TO CHANGES DURING PREGNANCY

By C SIDNEY BURWELL, M D , F A C P , *Boston, Massachusetts*

KNOWLEDGE of the general level of venous pressure may be usefully applied to the evaluation of cardiac failure and of pericardial obstruction and it may sometimes serve as a guide to the management of these conditions. These applications are widely known and practised. This communication is concerned, not with the general level of venous pressure, but with the study and utilization of local venous pressures in the understanding and description of disease. My colleagues and I were led to make the observations here reported by certain phenomena encountered during our study of pregnant women¹. During the physical examination of such patients observation was made of an increase in the number and prominence of visible veins over the abdomen, suggesting the development of a collateral circulation. Assuming that collateral venous channels develop in relation to some obstruction to venous blood flow, we undertook a comparison of the pressures in two widely separated portions of the venous system. These were the femoral vein and a vein in the antecubital space. These two points are approximately the same distance from the heart, moreover, one is in the system of the inferior vena cava and distal to the apparent collateral circulation, while the other is in the system of the superior vena cava.

Measurements of venous pressure were made by the direct method described by Moritz and von Tabora². The patient lay on his back in bed and the zero point of the manometer was set at a level 5 cm. dorsal to the fifth costal cartilage. It was found advisable to precede the measurement by a period of rest and to minimize discomfort by the injection of a drop of local anesthetic.

Only some observations by Runge,³ who compared arm vein pressure with that in veins near the knee, and the study of 11 patients with diverse conditions by Ferris and Wilkins⁴ offer information bearing on this point. Therefore, the arm and leg venous pressures were studied in a group of non-pregnant individuals, including normal persons and those with con-

* Read in part at the meeting of the Association of American Physicians, Atlantic City, New Jersey, May 5, 1937.

From the Department of Medicine, Harvard Medical School, and the Medical Service of the Peter Bent Brigham Hospital, Boston, Massachusetts.

ditions already known to affect local or general venous pressure The results of these preliminary observations are summarized in table 1

TABLE I
Examples of Venous Pressure in Arm and Leg in Normals and in Patients
with Various Circulatory Disturbances

| | | Venous Pressure | |
|---|--|---------------------|---------------------|
| | | Arm | Leg |
| | | mm H ₂ O | mm H ₂ O |
| A | <i>Normal circulatory system</i> 1 Psychoneurosis | 58 | 58 |
| B | <i>Heart disease</i> | | |
| 1 | <i>Without failure</i> | | |
| | 2 Hypertension (B P 210/110) | 42 | 41 |
| | (B P 212/140) | 48 | 55 |
| 2 | <i>With failure and without ascites</i> | | |
| | 3 Hypertension | 182 | 178 |
| 3 | <i>With failure and with ascites</i> | | |
| | 4 Aortic regurgitation and hypertension | 238 | 269 |
| 4 | <i>Pericardial obstruction</i> | | |
| | 5 Constrictive pericarditis | 320 | 304 |
| | 6 Pericardial effusion | 165 | 167 |
| C | <i>Mediastinal tumor</i> 7 Lymphoma of superior mediastinum | 360 | 60 |
| D | <i>Abdominal tumors</i> | | |
| | 8 Fibromyoma of uterus before operation | 104 | 274 |
| | Fibromyoma of uterus after operation | 66 | 55 |
| E | <i>Ascites not due to heart disease</i> | | |
| | 9 Cirrhosis | 105 | 146 |
| | Cirrhosis after removal of 5,000 c c | 88 | 88 |

In individuals without heart disease or local venous obstruction, the venous pressure is not elevated, and is nearly identical in arm and leg under the conditions of these observations. In patients with heart disease but without congestive failure or pericardial obstruction, the venous pressure is similar in arm and leg and is not elevated. In patients with manifest congestive failure and in those with pericardial obstruction from either fluid or constrictive scar the pressure is elevated. The pressure in such cases is identical (or nearly so) in arm and leg, unless there is a considerable accumulation of fluid in the abdomen. When ascites is present the leg pressure may be higher than the arm pressure. Removal of ascites in such cases results in similar pressures in arm and leg, at a level which is still above normal but often somewhat lower than the original arm pressure.

These impediments to venous flow are central, i.e. they are due to right ventricular failure or to pericardial obstruction and they interfere with the entry of blood into the heart. Obstruction may also be at some peripheral

point, in which case venous pressure may be elevated locally and may differ widely in arm and leg. Examples are given of a patient with a mediastinal tumor in whom the arm pressure is higher than that in the leg, and of patients with intra-abdominal tumor or noncardiac ascites in whom the leg pressure is higher than that in the arm. In some of these patients the collateral circulation led to the visible distention of superficial veins.

TABLE II
Pressure in the Veins in Arm and Leg of Women During and After Pregnancy

| No | Months of Pregnancy | Venous Pressure | | Time after Delivery | Venous Pressure | |
|----|---------------------|-----------------|------------------|---------------------|-----------------|------------------|
| | | Arm | Leg | | Arm | Leg |
| | | mm | H ₂ O | | mm | H ₂ O |
| 1 | 3 months | 58 | 78 | 6 months | 65 | 70 |
| 2 | 3½ months | 77 | 100 | | | |
| | 8½ months | 56 | 240 | Unknown | 108 | 97 |
| 3 | 4 months | 102 | 163 | 5 months | — | 118 |
| 4 | 6½ months | 85 | 154 | | | |
| | 7½ months | 98 | 175 | | | |
| 5 | 7 months | 156 | 208 | | | |
| 6 | 7 months | 102 | 232 | | | |
| 7 | 7½ months | 80 | 145 | | | |
| 8 | 8 months | 110 | 201 | 5 months | — | 102 |
| 9 | 8 months | 78 | 161 | 4 months | 108 | 92 |
| 10 | 8 months | 102 | 236 | 10 days | 108 | 72 |
| 11 | 8 months | 76 | 200 | | | |
| 12 | 8 months | 110 | 215 | | | |
| 13 | 8 months | 90 | 170 | 6 months | 30 | 30 |
| 14 | 8½ months | 51 | 183 | 6 months | 89 | 81 |
| 15 | 8½ months | 145 | 181 | 7 days | 91 | 87 |
| 16 | 8½ months | 95 | 220 | 1 month | 110 | 85 |
| 17 | 8½ months | 138 | 190 | 6 weeks | 118 | 97 |
| 18 | 8½ months | 82 | 188 | 6 days | 162 | 63 |
| 19 | 9 months | 62 | 265 | | | |
| 20 | "Near term" | 55 | 178 | | | |
| 21 | "At term" | 78 | 198 | | | |
| 22 | "At term" | 82 | 210 | | | |
| 23 | | | | 17 days | 48 | 55 |

With these observations in mind we may proceed to a consideration of the venous pressures in the arm and leg of pregnant women. Table 2 and figure 1 record observations in 22 women and in every case the leg pressure during pregnancy is notably higher than that in the arm. It is seen that by the fourth month of pregnancy the rise takes place and that it persists and even increases throughout pregnancy. The pressure falls abruptly to normal with delivery.

Similar observations were then made in pregnant bitches. The jugular vein was utilized instead of one at the elbow. It was found that the pressures in the femoral veins of these pregnant animals were higher than those in the jugular veins, and that the difference was comparable to that observed between arm and leg veins in pregnant women. After delivery the dif-

ference was not present When the pregnant animal's abdomen was opened the femoral venous pressure did not alter, which led us to conclude that the

FIG 1 Venous pressure in pregnancy

elevated femoral venous pressure was not due to an increase in general intra-abdominal pressure

Further observations were made concerning the relation of general abdominal pressure and the pressures in the femoral and jugular veins by the injection of salt solution into the peritoneal cavity of dogs An example of these experiments is shown in table 3 Two points may be noted

TABLE III

Venous Pressure in Femoral and Jugular Veins in Relation to Elevated Abdominal Pressures in a Dog

| C c Saline Injected in Peritoneal Cavity | Intra-Abdominal Pressure | Femoral Venous Pressure | Jugular Venous Pressure |
|--|--------------------------|-------------------------|-------------------------|
| | mm H ₂ O | mm H ₂ O | mm H ₂ O |
| 0 | | -2 | -4 |
| 300 | | +6 | -3 |
| 800 | +20 | +37 | -2 |
| 1400 | +60 | +72 | ±0 |
| 2000 | +145 | +148 | -1 |
| 2600 | 270 | 270 | -1 |
| 2800 | 345 | 342 | +2 |
| 3000 | 410 | 410 | +4 |
| 3200 | 490 | 495 | +11 |
| 3300 | 525 | 525 | +12 |
| All fluid removed from abdomen | | 0 | +8 |

Note The scales were set so that the zero point was at the level of the apex beat

1 The leg venous pressure does not rise until the general abdominal pressure begins to go up

2 When the leg venous pressure reaches a height comparable to that observed in pregnant women the abdominal wall is tense

Since the abdominal wall of pregnant women with a high femoral pressure is not tense it is evident that an increase in general abdominal pressure is not the mechanism leading to the elevated femoral pressure in pregnant women

These observations and those concerned with abdominal tumors suggest that an important factor in the high femoral pressure is the pressure of the gravid uterus upon the veins. This concept is borne out by the following observation in pregnant bitches. When the gravid uterus was lifted from its normal position in the abdomen and supported so that it did not press on the great veins the pressure in the femorals fell, although it still remained above the pressure in the jugulars

So much for venous obstruction. But the pressure in any vessel is influenced not only by the resistance to outflow but also by the amount and pressure of the blood flowing into it. This point may be illustrated by the situation existing in the veins adjacent to an arteriovenous fistula. In spite of the minimal resistance offered by normal veins the pressure in these vessels is markedly elevated, even some distance away from the fistula

FIG 2 Venous pressures at various points in a patient with a neoplasm of the superior mediastinum

There exists evidence that a large volume of blood at a relatively high pressure enters the venous reservoir by way of the placenta. Indeed it may be shown that the maternal placental circulation constitutes a modified arteriovenous fistula. There appears no reason to doubt that the factor of increased inflow is an important cause of the elevated femoral pressure

The knowledge of venous pressures acquired by these observations may be utilized in the study of conditions other than pregnancy. Two examples may be cited.

The first is a woman of 45 who entered the hospital with a history of increasing dyspnea and abdominal enlargement. The general evidence of heart failure was acceptable until it was observed that even after removal of the ascites the femoral venous pressure was higher than the arm (180 mm as compared to 115 mm). This led to a search for an obstruction to venous flow, which was subsequently demonstrated to be an intra-abdominal neoplasm riding directly over the inferior vena cava and partially occluding it. There were no physical signs, other than the differential venous pressures, which pointed to a tumor in this location.

The second patient is a man whose venous pressures are indicated in figure 2.

The venous pressures at these different points, even in the presence in this case of an equivocal roentgen-ray, point clearly to an obstruction in the superior mediastinum. Further roentgen-ray examination verified this localization.

We conclude from these observations

1 Venous collaterals develop when there is a higher venous pressure in one area of the periphery than in another.

2 The high pressures in the femoral veins of pregnant women are brought about by at least two mechanisms

- (a) The inflow of a large amount of blood via the placenta
- (b) Obstruction to venous outflow by the gravid uterus

3 The comparison of venous pressures in different parts of the body is useful in the understanding and description of disease and may on occasion even be applied to its diagnosis.

SPLENIC IRRADIATION IN THE TREATMENT OF PURPURA HEMORRHAGICA

By HAROLD W JONES, M D , F A C P , LEANDRO M TOCANTINS, M D ,
RICHARD MANGLES SMITH, M D , *Philadelphia, Pennsylvania*

OUR experience with splenic irradiation in purpura hemorrhagica is not in agreement with that of Mettier,¹ who states, "Repeated roentgen irradiation over the spleen in suitable doses is an excellent means of increasing the number of circulating blood platelets in patients with idiopathic thrombocytopenic purpura hemorrhagica "

EARLY RESULTS

The term control of coagulation was used loosely, and still is, by some to include control of bleeding of any type without attempting to isolate that occurring in purpura hemorrhagica. Therefore, many data reported in the literature can not be considered as significant. Costa Storico² states that as early as 1912 Triboulet, Weil, and Parof report favorably on the use of splenic irradiation in hemorrhage. Stephan,³ in 1920, noted the cessation of bleeding following its use and considered the spleen as the central organ of coagulation. He includes in his report the results of Bucky and Guggenheimer. Aubertin, Levy, and Lereboullet,⁴ using an irradiation of 200 R over the spleen, reported the control of the bleeding time followed by a platelet increase in a patient with rheumatoid purpura. Schneider,⁵ in 1929, reported favorably on the use of this method, but the blood studies are not complete. In 1932 Hippe and Kochmann⁶ stated that excellent results in this disease were obtained by Klempere, Goia, and Bignoni and they conclude, "Through our experience we have reached the point not to lose any time with other treatment in the case of severe thrombopenic bleeding, but irradiate the spleen at once." In 1935 Mettier, Stone, and Purviance⁷ report on the use of irradiation in eight patients, stating that there was a cessation of bleeding and a prompt and satisfactory rise in platelets. Rudisill²¹ reports similar results in seven patients.

Pancoast, Pendergrass, and Fitz-Hugh,⁸ in 1925, report that Corey and Mandelstaum were unable to obtain an effect similar to those already described. Hippe and Kochmann⁶ state that Korger, Leschke, Wittkower,

*Read before the Section on Medicine, College of Physicians of Philadelphia

Received for publication September 16, 1937

Prepared in part under the J. Ewing Mears Research Fund and in part through the generosity of Mr. Charles Groff, of Greenwich, Conn.

We are indebted to Miss Virginia Mitchell for collection of many data relating to this subject and to Mr. Eric Plehn for the translation of many articles in the bibliography and others not included.

Mandelstaum and Pakozdy completely declined the use of roentgen-ray for the treatment of thrombopemic purpura Thormann,⁹ in 1928, pointed out that Dolbe and Wertheim criticized the use of irradiation of the spleen in this disease and that Kleistadt had no success in treating essential thrombopemic purpura by this method, and that furthermore Passon felt that splenic

FIG 1 J C Adequate roentgen-ray to spleen administered from February 15 to March 23 No effect upon platelets or hemorrhagic phenomena Splenectomy March 24 Patient well in all respects August 11, 1937

irradiation should not be used in the case of children Schneider,⁵ in 1929, notes that Meda was entirely unsuccessful in treating this disease by this method Marzullo,¹⁰ in 1933, failed to find any significant clinical improvement in his patients after roentgen-ray therapy, and further states that the platelets did not rise above 100,000 Pancoast, Pendergrass and Fitz-Hugh report their results as inconclusive with this form of treatment, all cases coming to splenectomy

RATIONALE

Two functions of the spleen seem to be well established, (1) the reservoir function, and (2) the destruction of red cells, granulocytes and platelets by the clasmatocytes of endothelial origin in the spleen One wonders how the cells of the spleen are able to pick out the platelets and destroy them and not destroy the granulocytes and red cells at the same time We know,

however, that in malignant neutropenia the granulocytes are few in number and the platelets remain at a practically normal level. In hypoplastic anemia and aleukia hemorrhagica both platelets and granulocytes may be reduced to a very low level. This leads us to consider the condition of the bone marrow, in which we find the megakaryocytes normal in number in some purpuric patients and reduced in others. Probably the number of

FIG 2 J P Chronic purpura with acute exacerbations. Roentgen-ray to spleen ineffective. January 1936 developed middle ear disease, mastoiditis, painful and swollen joints, erythema nodosum (purpura rheumatica). Following this the platelets rose to normal, bleeding time fell to normal. Platelets dropped to a low level a month later, rose again while patient was in Arizona. Menstrual cycle established, periods normal. Platelet level at present normal, no hemorrhagic phenomena.

megakaryocytes is not as important as the functional ability of the megakaryocytes that are present in the bone marrow at a given time. More study should be given to the condition of the megakaryocytes as well as to their actual number.

It seems unlikely that the platelet lack in purpura hemorrhagica can be explained purely on the basis of the collection of "hyaline" masses of platelets in thrombosed capillaries, as described by Baehr,¹¹ if roentgen-ray to the spleen is an effective form of treatment. It may be, however, that depressing or removing splenic function in some way permits some of these

platelets to get back into circulation Does the spleen have a depressing effect on platelet formation in the bone marrow? This seems unlikely and presumes the presence of a splenic hormone The importance of anoxemia in bone marrow erythrocytic development is well established and may play

FIG 3 J G Chronic purpura Snake venom administered over a three month's period before roentgen-ray treatment to spleen Following this platelets rose to a high level after the fourth treatment and reached a peak after the fourteenth, then fell to 6,000 per cu mm on November 27 Roentgen-ray treatment discontinued because of the accompanying drop of white cells to 2,700 Additional treatment increases total R units to 1620

a significant part in megakaryocytic activity Schurer¹² discusses the wide usage of splenic irradiation in treatment of cases of "septic disease," noting favorable results The dosage is not mentioned, but he concludes that the good effect obtained is due to an outpouring of white blood cells as a result of lymphatic damage or as a result of an irritating effect on the reticulo-endothelial system, thereby increasing the function We see, therefore, that one group use roentgen-ray to depress the function of the clasmatoocytes and another to stimulate the reticulo-endothelial system, of which the splenic clasmatoocyte is a part Who is able to determine the dose of roentgen-ray to the spleen which may stimulate in one case and depress in another?

EXPERIMENTAL

Using $\frac{1}{4}$, $\frac{1}{2}$ and 1 erythema dose with filters of 1 Al, 0.3 Cu, 5 Al and 2 Al in rabbits and injecting 1 cc of iron oxide intravenously, Schus-

terowna¹³ concludes that the cells of the reticulo-endothelial system in the spleen were less able to absorb iron and, therefore, possess less phagocytic ability. Cosati,¹⁴ using 100 R to the exteriorized spleen at 13 cm with slight filtration, failed to find evidence of marked splenic destruction sufficient to endanger gross splenic function. From this work it would seem

FIG 4 J G (cont'd) Platelets continued at low level until March 14, at which time the child developed croup with temperature rise for a period of 10 days. During this time a platelet rise occurred, which has continued to the present time. The hemorrhagic phenomena also have disappeared.

likely that the so-called roentgen-ray splenectomy is not possible with the doses used in clinical medicine.

DOSAGE

Hippe and Kochmann,⁶ who employed a dose of from 100 R to 180 R, felt that one should not waste time with other forms of treatment in severe thrombopenic bleeding, but should irradiate the spleen at once. They report a marked increase in blood platelets and a cessation of the hemorrhagic phenomena, and quote Nonta who gave 10 doses of 500 R to a five year old girl with this disease with resultant increase in platelets and cessation of the hemorrhage. Thormann⁹ reports the control of hemorrhage in three patients, by means of a dose of 500 R. Costa Storico, using 100 R to 150 R for two to four doses, reports on the cessation of the hemorrhagic phe-

nomena in two patients. Mettler⁷ recommends a dosage of 200 R to 300 R daily until 1,200 R to 3,300 R are given in six to 15 days. One of his patients had a recurrence of the hemorrhagic phenomena and a reduction of platelets, and a second roentgen-ray series was given with similar good results. We note, however, that the patient took the drug Sedoimid each time

FIG 5 R S Chronic purpura. Roentgen-ray to spleen ineffective. Acute abdominal pain, marked fall in red cells, and probable intra-abdominal hemorrhage occurred during the treatment. A short time later splenectomy was successfully performed. Additional treatments to spleen not included in chart bring total to 3591 Rn.

before the hemorrhagic phenomena appeared. Pancoast, Pendergrass, and Fitz-Hugh⁸ used a dose of approximately 160 R without convincing results.

In our series of 11 patients the dose varied from 54 R to 500 R without the favorable results reported by other observers.

EVALUATION OF THERAPEUTIC MEASURES

Amatus Lusitanus¹⁵ described the first case of this disease in 1556, and Willan¹⁶ gave it the name of purpura hemorrhagica in 1801. Many therapeutic measures—purging, bleeding, tincture of iron chloride, injections of whole blood, injections of serum, and others, have been enthusiastically recommended. In the last few years Peck¹⁷ has used snake venom successfully in this disease, but in our hands it has not been efficacious. Anti-

venin has been recommended by Taylor,¹⁸ but we, as well as others, have found it of no value Congo red intravenously, viosterol by mouth, liver extract by mouth and intramuscularly all have their advocates, but in our experience they have not been helpful¹⁹ With regard to liver extract, we

FIG 6 Br M W Acute purpura treated by transfusion with temporary improvement March 2, with bleeding time at 32 minutes, roentgen-ray treatment was administered March 4 a massive dose of roentgen-ray was given, following which retching and vomiting occurred The patient's face became suffused with petechiae at each spasm, intracranial hemorrhage resulted, followed by death

have used it in many patients and have failed to get the results reported by others until recently, when one of our patients developed a satisfactory platelet rise after it had been administered for several days Did the liver extract influence the platelet rise, or was it coincidental? Students of this disease are well aware of the large number of spontaneous cures In our group, 15 patients are included under this heading We have knowledge of two patients, one in extremis, who had a sudden cessation of hemorrhagic phenomena and platelet rise after being anointed, and a second who had a similar experience after a visit from a hex doctor Patients who develop hemorrhagic phenomena and a platelet drop as a result of drug sensitivity frequently have a dramatic increase in platelets after the drug is withdrawn

(Sedormid) As has been pointed out emphatically by Dr J H Pratt,²⁰ whose experience in this disease is very extensive, one must evaluate all forms of treatment in this disease, with particular consideration of the chance of the coincidental spontaneous cure

CASE REPORTS

In this presentation we report on nine patients who we believe received adequate roentgen-ray therapy and three who received the treatment, but not in sufficient amount to be conclusive. In none of these were we able to obtain favorable results comparable to those reported by other observers

DOSAGE

Our erythema dose is considered to be 800 R measured in air. The equipment delivers approximately 54 R per minute measured in air, using a filter of $\frac{1}{2}$ mm of copper, 2 mm of aluminum. Usually the anterior splenic area is rayed one day and the posterior the next. The following is a brief report of the various patients studied with the result as far as the blood findings are concerned. None of the patients studied had a cessation of hemorrhagic phenomena after roentgen-ray therapy

CASE REPORTS

Case 1 C S, male, aged 3

Chief Complaint Spontaneous hematomas, bleeding from nose and ears, petechiae, and ecchymosis

Family History Negative

Past History Symptoms present since one year of age, otherwise negative except for frequent "colds" and middle ear disease

Present Illness One month before admission to the hospital, in 1935, acute hemorrhagic symptoms developed

Physical Examination Spleen and liver not enlarged. General systemic examination negative except for conditions mentioned

Diagnosis Chronic purpura hemorrhagica with acute exacerbation. Not benefited by roentgen-ray therapy

Case 2 E E, male, aged 12

Chief Complaint Epistaxis, petechiae, and ecchymosis for three years

Family History Negative

Past History Negative

Admitted October 30, 1935

Physical Examination Petechiae and ecchymosis on face, arms and legs Liver and spleen not palpable

Diagnosis Chronic purpura hemorrhagica Roentgen-ray treatment ineffective

Case 3 J M, male, aged 10

Chief Complaint Bruising, nose bleed

Family History Negative

Past History Measles, easy bruising in 1932 Patient states that he had nose bleed at the change of seasons The hemorrhage was so severe at times that he became unconscious He states that he does not bruise unless he injures himself

Admitted May 18, 1937

Diagnosis Chronic purpura hemorrhagica with acute exacerbation Roentgen-ray treatment ineffective for control of hemorrhagic phenomena and increase in platelets

Case 4 J C, male, aged 14

Chief Complaint Bleeding from nose, petechiae, and ecchymosis (general)

Family History Negative

Past History Chicken pox and measles In 1928 patient was hospitalized because of repeated nose bleed The nose bleed, petechiae and ecchymoses continued at various intervals until 1936, when patient was admitted to another hospital, at which time the blood loss from the nose was unusually severe following a cold There was some bleeding from the gums at this time

Present Illness On admission, February 15, 1937, the patient had been bleeding from the nose for some days There was marked ecchymosis of the arms and legs and bleeding from the gums The spleen was palpable, the liver not felt

| 3/24/37 | Splenectomy | | | | |

Diagnosis Chronic purpura hemorrhagica with acute exacerbation Roentgen-ray treatment ineffective

Case 5 R C, male, aged 7

Chief Complaint Weakness, bleeding from gums, ecchymoses, and petechiae

Family History Negative

Past History Measles, pertussis, pneumonia, frequent attacks of tonsillitis
Tonsillectomy two years previously, no excessive bleeding

Present Illness Admitted June 1, 1926 Patient, bleeding extensively from gums, fell in the street and was brought to the hospital

Physical Examination Gums oozing, legs and thighs covered with ecchymoses and petechiae Spleen is palpable, liver not felt

July 16, after treatment with transfusions, roentgen-ray therapy was administered in a dose of approximately 540 R Unfortunately no platelet counts are available on this day The last platelet count recorded was on June 23, at which time the platelets were 88,000 On June 21 the hemoglobin was 88 per cent red blood cells 4,700,000, white blood cells 6,400, platelets 334,000

The patient was improving continually at the time of roentgen-ray Hemorrhagic phenomena had disappeared and the platelets were increasing In our opinion there was no indication for roentgen-ray therapy, nor was there indication for splenectomy, which was performed on the 28th of July The patient died November 23, 1926, during a re-admission to the hospital, when a diagnosis of osteomyelitis and broncho-pneumonia was made

Case 6 J D, male, aged 53

Chief Complaint Epistaxis

Family History Negative

Past History Smallpox at 5, bruised easily for the past 8 or 9 years

Present Illness November 1933 spontaneous nose bleed Admitted to the hospital January 27, 1934 A cold in the head brought on a severe hemorrhage January 26 On admission purpuric spots were present in the mouth and the extremities and there was bleeding from both nasal passages Various forms of treatment were used—transfusion, liver extract, snake venom, and others

Diagnosis Chronic purpura hemorrhagica with acute exacerbation Roentgen-ray treatment ineffective

Case 7 P S, female, aged 45

Admitted March 1921, in extremis, bleeding from mucous membranes, nose, mouth, vagina Ecchymoses and petechiae were present

Her hemoglobin was 30 per cent, red blood cells 2,000,000, white blood cells 8,600, platelets 16,000 Roentgen-ray was administered over the spleen in a dose of 500 R, but she died in 48 hours, although transfusions were used

Case 8 R S, female, aged 23

Chief Complaint Bleeding from nose and gums since age 6, excessive menstruation since age 14, tendency to bruise easily since age 6, long bleeding from cuts since age 6, weakness, dyspnea and palpitation, and swelling of ankles for three years

Family History Negative

Past History Measles, pertussis, frequent headaches, tendency to head colds Tonsils treated by electro-coagulation six years ago

Present Illness Admitted Oct 1935 Frequent spontaneous nose bleed since age of 6, occurring daily until onset of menses, then about one every two weeks, lasting one to two hours At age of 20 the nose bleed occurred once a month Spontaneous bleeding from the gums since age 21 Fourteen teeth have been extracted in the last two years, bled two to four days after each extraction

Physical Examination Spleen slightly enlarged, liver not palpable Petechiae and ecchymoses present on lower extremities Some tenderness in right lower quadrant

Roentgen-ray treatments daily from October 30 to November 12, except Sundays Seven anterior spleen 216 R, one 162 R, one 108 R, one 135 R Seven posterior spleen, five at 216 R, one at 162 R, one at 108 R One lateral spleen at 108 R, one left and right lateral chest 108 R each

Diagnosis Chronic purpura hemorrhagica Roentgen-ray treatment ineffective

Comment On October 19, following roentgen-ray to the spleen, the patient developed acute abdominal pain associated with marked fall in red cells of more than 2,000,000 per cubic mm. There was distinct abdominal tenderness, rise in temperature, and an increase in the white cell count above her usual level. The differential count showed a decided shift to the left. We felt that she may have had an intra-abdominal hemorrhage as there was evidence of free fluid in the abdominal cavity. The roentgen-ray treatments were discontinued.

Case 9 J. G., female, aged four

Chief Complaint Easy bruising, nose bleed

Family History Negative

Past History Always healthy until present illness

Present Illness Admitted October 1935. At two years of age child had severe infection involving nose, throat, and sinuses. This condition was present for four or five weeks. Since then she has bruised easily, has had many head colds with frequent nose bleed and one profuse hemorrhage from bowel.

Physical Examination Bruises and petechiae present on the arms, lower extremities and the body. Spleen and liver are both palpable, although not materially enlarged.

Thirty roentgen-ray treatments to the spleen anteriorly and posteriorly, total 1,620 R

The rise in blood platelets which occurred from October 14 to October 17 was followed by a drop from that date until October 23, at which time they rose to a high point of 218,000 on the 28th of October. From this time on, in spite of roentgen-ray treatment, the platelets fell to a low level of 6,000 on November 27. The white blood cells also dropped to a level of 2,700, and it was decided to discontinue roentgen-ray therapy. It seemed at that time that the roentgen-ray was bringing about a rise in blood platelets and the roentgen-ray treatment was discontinued from the 30th of October until November 9. From that time on there was no favorable effect from the use of roentgen-ray.

It would seem to us that this patient should be included along with the others as roentgen-ray treatment ineffective. Possibly a more optimistic observer might include this one patient under the heading of "questionable roentgen-ray effect."

Case 10 E S, male, aged 7

Chief Complaint Recurrent nose bleed for five months

Family History Negative

Past History Pertussis, mumps, varicella, pneumonia

Present Illness Admitted March 1936. Began to bruise easily at 5 years of age. The summer of 1935 he was in another hospital and was transfused repeatedly. Since September 1935 has had slight attacks of nose bleed, but in the last two weeks he had 6 severe attacks, one on the morning of admission.

Physical Examination There is bleeding from the left nasal passage anteriorly and posteriorly. Tonsils are large and seem to be infected. Spleen and liver are not felt. Petechiae and ecchymosis are present.

Roentgen-ray treatment ineffective with regard to control of hemorrhagic phenomena and platelet increase

Diagnosis Chronic purpura hemorrhagica with acute exacerbation

Case 11 J P, female, aged 12

Chief Complaint Easy bruising, nose bleed

Family History Negative

Past History German measles, mumps, tonsils and adenoids removed at age 7, no excessive bleeding Patient admitted September 1935 The first evidence of this disease occurred June 1935, petechiae were present on both ankles Easy bruising had been present two or three weeks previous Patient treated in another hospital by transfusions, injections of whole blood, and intramuscular injection of pentnucleotide

Physical Examination This examination revealed the presence of petechiae, ecchymoses, spleen and liver not enlarged

Roentgen-ray treatments given daily from September 25, 1935, to October 15, 1935 (except September 29, October 6, 8, and 13) on spleen, alternating every other day from anterior to posterior Seventeen treatments given Total of 1,431 R units on anterior and 1,188 R units on posterior

Diagnosis Subacute purpura hemorrhagica Roentgen-ray ineffective

DISCUSSION

It is evident from this study that the response to roentgen-ray in the patients which we present has been ineffective One might stretch a point and give credit to the roentgen-ray for an increase in platelets in one patient (J G), but this platelet increase did not hold and was not continued after further roentgen-ray treatment

Mettier recommends a dosage of from 200 R to 300 R It is true that we have not given this dosage to all of our patients However, other observers have obtained results comparable to those of Mettier with a smaller dose In many of our patients we have administered large doses, that is, 200 R without favorable response It seems fair to conclude that we have given roentgen-ray a suitable trial in the patients who came under our direction The response has been disappointing

Viewing the subject from a broader standpoint, we draw attention to brilliant reports as to cessation of hemorrhagic phenomena and improvement in the platelet numbers by other observers using various forms of treatment, for example, Herron and MacElroy¹⁹ obtained excellent results using auto-lyzed liver extract (Squibb) by mouth In our experience, with one exception, and this result is questionable, we were unable to duplicate their results We do not doubt the results which Mettier and some others have obtained We do, however, disagree with the statement that roentgen-ray to the spleen in suitable dosage is a satisfactory method of controlling hemorrhagic phenomena and of increasing the number of blood platelets We assert that this is an unfortunate statement for it leads the general medical

public to assume that all cases of idiopathic hemorrhagic purpura will be affected favorably if adequate roentgen-ray dosage is administered to the spleen. It seems probable that there are certain patients with this disease who will respond in a manner such as described by Mettier and others, and that there are other patients with the same disease who will fail to respond to adequate roentgen-ray treatment.

When this paper was read before the Section on Medicine of the College of Physicians of Philadelphia, Dr Fitz-Hugh, in the discussion, stated that he felt the only satisfactory treatment for this disease was splenectomy. Such a statement is, in our opinion, just as unjustifiable as that which Mettier makes with regard to the use of roentgen-ray. At present there is no single treatment for this disease that is eminently satisfactory. Students of this condition know that many patients who have been splenectomized have recurrences. Our plan of treatment is as follows:

If the patient is not in a dangerous state from loss of blood, we give him an opportunity to recover without any special form of treatment. If there is a considerable anemia or a progressive anemia, small transfusions are used. These are given every two or three days, or at times more often, or in larger doses. Vitamin C intravenously is given in selected cases. Liver extract intramuscularly and by mouth is also used. We intend to continue the use of snake venom and roentgen-ray in sufficient dose in all patients in whom we think it is safe, and finally, when all other measures fail we resort to splenectomy.

We wish to call attention again to the danger of roentgen-ray therapy, as is suggested by the effect which we noted in two of our patients: one, R S, who had an acute intra-abdominal condition with a sudden drop in red blood cells following roentgen-ray therapy, and second, the patient with a long bleeding time, who developed intracranial hemorrhage and died after roentgen-ray treatment, probably as a result of retching and vomiting (chart 6).

CONCLUSIONS

1 Roentgen-ray treatment to the spleen in adequate dosage is not a satisfactory form of treatment in all patients with this disease.

2 Purpura hemorrhagica is a disease in which spontaneous cure is frequently seen.

3 Many forms of treatment have been set forth as efficacious in this disease, but when tried by others have been found to be useless.

4 Patients receiving roentgen-ray therapy may become nauseated and vomit. This increases intracranial pressure and intracranial hemorrhage may result, especially if the bleeding time is long.

5 It seems probable that the patients with this disease may fall into a variety of groups, depending upon their response to various forms of treatment. One observer may be successful with a certain form of treatment in a few patients and another observer may be unsuccessful because he is not treating that particular variety of purpura hemorrhagica.

6 Roentgen-ray therapy in this disease, in dosage as set forth by Metier, should be used in selected cases, with the knowledge that it may not be efficacious in the particular patient under treatment

7 An estimation of the platelets in venous as well as in cutaneous blood may be of help in explaining some of the discrepancies between bleeding time, hemorrhagic phenomena, and platelet number

THE EFFECTS OF INSULIN HYPOGLYCEMIA UPON THE DIABETIC HEART IN CHILDREN AND YOUTH *

By HOWARD F. ROOT, M.D., F.A.C.P., *Boston, Massachusetts*

INTRODUCTION

THE possibility that harmful effects upon the heart may be produced in diabetic patients by the use of insulin has rested upon the occasional anginal attack after the administration of insulin to cardiac patients. Transitory changes in the electrocardiogram have been noted after the administration of insulin, suggesting some change in the heart muscle. It must be remembered that the injection of insulin into the body in a sufficient quantity to produce hypoglycemia, brings about changes, varying with the individual, the amount of insulin injected, the state of the counter-regulatory system, and undoubtedly other factors. When the blood sugar reaches a sufficiently low level, an increased output of adrenalin occurs, raising the blood pressure, increasing the pulse rate, stimulating the metabolism and tending to counteract the hypoglycemia by the liberation of glucose from the glycogen in the liver. The possibility that these effects may be dangerous in a patient with a heart seriously damaged by coronary disease has been emphasized disproportionately and little attention drawn to the probability of the generally advantageous effect of insulin properly administered. Whether there is any harmful effect upon the healthy heart is an entirely different question.

In this paper are reported the results of a series of electrocardiograms taken in young patients receiving insulin. Attempts were made to obtain electrocardiograms when the blood sugar was high as well as during a period when the blood sugar was low, but before serious symptoms of insulin shock had occurred. In several of the patients mild insulin reactions did occur a few minutes after the electrocardiogram had been taken (usually between 11:30 a.m. and 12 o'clock noon). The object was not to demonstrate effects produced by serious or extensive hypoglycemia with unconsciousness or convulsions but rather to observe changes, if any, occurring during the rapid reduction of the blood sugar by means of injected insulin.

In addition to these observations upon the electrocardiograms of young patients, one patient is reported who was seen in consultation by the writer after she had received by error an overdose of insulin which proved to be fatal. A complete autopsy was made and the results are here summarized.

* Received for publication August 16, 1937

ELECTROCARDIOGRAPHIC DATA

The patients were 13 males and 12 females, varying in age from seven years to 46 years, only two were over 25 years of age. None of these patients gave a history of rheumatic fever or of any infection usually related to heart disease, nor in any of these cases was there clinical evidence of any cardiac lesion. The duration of diabetes in these cases varied from 0.1 year to 14.2 years.

Electrocardiograms were taken with the three conventional leads and a fifth lead from the cardiac apex to the left leg, these are summarized in table 1.

The electrocardiograms were taken usually after breakfast in the morning and again shortly before noon, except in those instances where only a single record is available. Immediately after the electrocardiograms were taken, determinations of the capillary blood sugar were made. The insulin was administered just before breakfast in doses varying from 20 to 50 units.

The cardiac rate per minute varied from 55 in Case 4111, a male, 46 years of age, to 120 in the case of a 13-year old boy, Case 9769. No striking relationship between the heart rate and the blood sugar values could be seen, probably because no severe insulin reactions occurred. It is notable that in severe insulin hypoglycemia a slow pulse often occurs.

Case 6930, aged 19 years, entered the hospital August 8, 1937, unconscious, in an insulin reaction with a blood sugar of 50 milligrams per 100 c.c. He had taken insulin at 2.00 a.m., risen at 10.30 a.m. in a confused state evidently due to hypoglycemia, taken a second dose of unknown amount and arrived at 2.30 p.m. Even after the injection of 35 c.c. of 50 per cent glucose which raised the blood sugar to 130 milligrams, the pulse rate remained at 62. He fought and struggled with attendants but the pulse remained at 62. However, 30 minutes later, when he suddenly came to normally, the pulse quickly rose to 72. This seemed clearly a bradycardia due to a vagus stimulation associated with the general hypoglycemia effect upon the central nervous system.

The rhythm was slightly irregular in every case except in the three oldest patients, Cases 4568, 14405, and 4111. All younger patients showed a sinus arrhythmia, which was present whether the blood sugar was high or low. Extrasystoles of ventricular origin occurred with some frequency in a girl aged 14 years, Case 14491. The absence of extrasystoles in the remaining curves is notable.

Changes in conduction time were conspicuous by their absence. The P-R interval varied from 0.12 to 0.16 second. In two cases this interval was increased with hypoglycemia and in two cases it was shortened. The Q-R-S time varied from 0.04 to 0.08 second. Slight prolongation was noted in five cases and shortening of the interval in three cases. The S-T time varied from 0.22 second to 0.32 second. In five cases it was slightly prolonged and in three slightly shortened with fall in blood sugar.

The maximal height of the R-wave was found to vary from 5 millimeters in Case 9769, a boy 13 years of age with severe diabetes and a large

liver, to 38 millimeters in a boy 11 years of age, Case 6113, also a severe case of long duration. The R-wave was maximal in the fifth lead in 30 records, in the second lead in 13 records and in the first lead in 7 records. Changes in the elevation of the R-wave occurred with changes in the blood sugar in a few instances. In four cases, with the fall of the blood sugar during the action of the insulin, the elevation of the R-wave increased, and in five it was diminished.

The deflection of the Q-wave was measured in four leads. Q-waves were absent in at least one lead in all patients, with two exceptions. Very deep Q-waves were observed in three records of Case 6113, a boy of 11 years, with diabetes of long duration. In Lead V the Q-waves were often of great depth, varying from 0 to 28 millimeters.

The T-waves were upright in all cases in the first two leads. There were no striking changes in the T-wave in the first lead. In the second lead, four cases showed a deflection of 1 millimeter or less in the second lead, T-wave. The T-wave in the third lead was flat in five cases and inverted in nine cases. With a fall in the blood sugar, there was a fall in the height of the T-wave in nine cases, but in three the T-wave increased in amplitude while the blood sugar fell. In eight cases there was no change in the T-wave with a change in the blood sugar.

The T-waves in the fifth lead were upright in 10 cases and flat in two cases. With a falling blood sugar due to insulin, there was a lowering of the T-wave in this lead in five cases, in six cases, no change occurred and in two cases the T-wave rose with the falling blood sugar.

W-forms of the Q-R-S intervals occurred in a number of cases as well as inversion of the T-wave or of the entire complex in the third lead.

Miscellaneous changes may be noted. In Case 13395, a girl seven years of age, as the blood sugar fell a more marked depression of the S-T interval in the fifth lead occurred. The T-wave was upright in all four leads. In Case 11905 a variation in the form of the complexes occurred. The early leads were characterized by a lower R-wave and a higher T-wave than later leads. At this time the blood sugar level was 0.07 per cent. Also, in this curve the T-wave in the third lead varied somewhat, being slightly inverted or diphasic in certain cycles. A slightly depressed S-T interval was noted in Case 12190, while the blood sugar was 0.07 per cent and especially in Case 8156, a girl 15 years of age with severe diabetes. Slight notching in the R-wave of the second lead with slurring of the R-wave in the fifth lead occurred in the record of Case 4568, a girl 25 years of age with uncontrolled diabetes of 14 years' duration.

In summary, it may be said that the electrocardiographic changes noted in these cases are slight and not clearly correlated with the intensity of insulin action as indicated by variations in the blood sugar. This lack of correlation is intensified if one compares the mild degrees of hypoglycemia in this series with the severe and prolonged hypoglycemia of the series

reported by Hadorn¹ and de Chatel and Palisa² Actually the blood may contain no glucose without symptoms therefrom as reported in the review by Marble¹⁴

ABSENCE OF CARDIAC PATHOLOGY IN FATAL HYPOGLYCEMIA

The effect of a fatal dose of insulin is illustrated in the following case report

CASE REPORT

Miss D, Case 12882, aged 27 years, had been treated with insulin since the onset of diabetes in 1928 On August 9, 1934, she returned to her home from work, behaved queerly, and rapidly became unconscious During the next 12 hours, 200 units of insulin were given and she had convulsions At noon on August 10 she was unconscious and cyanotic with irregular gasping respiration, and immediately 40 c c of 50 per cent glucose solution were given intravenously Respiration became regular, cyanosis disappeared and the pulse rate, at first 144, fell almost to normal, but at no time did she regain consciousness Her muscles were at times in tonic contraction and there was a suggestion of the opisthotonus position A double Babinski sign was present The pupils were dilated All normal tendon reflexes were somewhat exaggerated Lumbar puncture showed clear fluid with a pressure of 650 mm, a trace of globulin, 30 cells, no sugar was present The analysis of the spinal fluid was carried out at the New England Deaconess Hospital, using a slight adaptation of the Folin technic for blood sugar determination Laboratory blood sugar analyses were as follows

| Date | Time | Blood Sugar (%) |
|-------------|------------|-------------------|
| August—1934 | | |
| 10 | 8 00 a m | Too low to read |
| 10 | 10 30 a m | Too low to read |
| 10 | 12 30 p m | Too low to read |
| 10 | 3 30 p m | 27 mg in 100 c c |
| 11 | 7 00 a m | 500 mg in 100 c c |
| | at autopsy | 540 mg in 100 c c |

TREATMENT

She received during 18 hours, 600 grams of glucose in solution intravenously or under the skin At first it was given in 50 per cent solution, 40 c c at a time Later a cannula was tied into a vein and glucose solution continuously administered Adrenalin did not help

During the first 20 hours, no urine was obtained At the end of this time, 3 ounces were obtained by catheter in which the chloride concentration was 0.2 gram per 100 c c During the last 12 hours of her life, the blood sugar was high, and the urine contained much sugar Bladder urine at autopsy contained 6.8 per cent sugar She never regained consciousness and died 39 hours after onset of hypoglycemic symptoms

Pathologic Report The gross appearance of the brain as well as of all other tissues was normal, except for slight edema possibly due to the prolonged administration of glucose solution

Microscopical examination was negative except for the tissues described below

Heart Slight edema and some perivascular fibrosis

Lung Congestion and some edema Rare polymorphonuclear leukocytes, in alveolar walls together with mononuclear leukocytes in alveoli

Spleen Moderate congestion

Pancreas Acinar and duct tissue negative Islands reduced in number and in size One or two show hypertrophy of so-called "cobra" type

Liver Moderate central congestion Glycogenic vacuolization of a few nuclei in periportal hepatic cells

Adrenal Moderate lymphocytic infiltration of medulla Usual distribution of lipid in cortex

Kidney Moderate congestion No evidence of glycogenic vacuolization

Aorta Some swelling of subintimal ground substance with early lipid deposition Few mononuclear phagocytes present, many of which contain considerable amounts of lipid, others of which apparently had been migrating

Brain Slight subpial and perivascular edema Pons negative Cerebellum negative

DISCUSSION

Electrocardiographic Changes The youthful diabetics of this series receiving small doses of insulin without any serious clinical evidences of hypoglycemia, show some electrocardiographic changes, but these changes are slight, inconstant and of little consequence

In agreement with our findings are those reported by Hadorn¹ and by de Chatel and Palisa² in two series of patients studied during the severe prolonged hypoglycemic states produced by insulin in treating schizophrenia

(1) Hadorn had an opportunity to make 47 observations upon 31 patients undergoing the hypoglycemia treatment for schizophrenia. At the lowest levels, the blood sugar values reached were under 20 milligrams per 100 c.c. His patients were all between the ages of 20 and 40 years with the exception of five whose ages were from 43 to 54 years. The insulin injections were given intramuscularly, the dose varying between 10 and 200 units. He had no cases of initial hyperglycemia. In 21 of Hadorn's cases the pulse rate increased to 100 and in 11 cases it became slowed to 50. In 10 cases there was no change in the pulse rate. The pulse rate did not seem to run parallel to the degree of lowering of the blood sugar. Often, the increase in heart rate occurred shortly after the insulin injection and not at the time of the hypoglycemia. Many times it also occurred that the increased heart rate did not develop until after the noon-day meal or even after the evening meal. In one case, the tachycardia lasted for several weeks. In a majority of Hadorn's cases slight increase in systolic blood pressure occurred, 10 to 20 millimeters, and usually the diastolic pressure fell. In three experiments the blood pressure rose to levels of 170 to 180. Only exceptionally did disturbances of the rhythm occur. The changes observed by Hadorn in the electrocardiograms of his patients may be summarized as follows:

1 The T-wave was inverted once and the P-R interval became shorter in the cases where the pulse rate rose. In 18 cases the P-Q interval was increased by 1/100 to 1/200 of a second and in eight cases it was shortened. The Q-R-S complex was unchanged in 22 cases, was shortened in six and lengthened by 1/100 second to 3/100 in three cases.

2 The S-T interval was unchanged in 26 cases and in 16 cases there was a depression of the S-T interval. The frequency of this depression of the S-T interval is in contrast to the findings of de Chatel.²

3 In only 10 cases was the T-wave unchanged. In 32 cases there was more or less marked lowering of the T-wave.

4 The Q-T interval was lengthened in 32 cases. In six cases a U-wave or a doubling of the T-wave occurred.

The observations made by de Chatel and Palisa² were in a series of cases of severe induced hypoglycemia, often with coma and convulsions. In these states the

authors noted occasionally a flattening and a lowering of the T-wave, a broadening of the Q-R-S complex and appearance of a sinus arrhythmia, various extrasystoles, auricular fibrillation, prolongation of the conduction time. Against the theory of glycogen impoverishment is that rabbits' heart muscles even with great doses of insulin do not become more glycogen poor. Further, the electrocardiographic changes are not relieved by the administration of grape sugar and, finally, that they do not appear with spontaneous hypoglycemia. However, certain cases, even after the largest insulin doses, show no electrocardiographic changes in the severest types of hypoglycemic shock, and the others may show only a lowering of the T-wave. As a rule, the changes develop within 45 minutes and last for half an hour to an hour after the cessation of the unconsciousness. They were all quite similar and consisted in the lowering of the T-wave. The thoracic lead from the back to the precordium is exceptionally sensitive and at times shows a complete reversal of the T-wave after insulin whereas de Chatel and Palisa did not observe this phenomenon either in the first, second or third leads. In two of their 19 cases there was a sinus arrhythmia. The changes stand in no quantitative relation with the severity of the insulin shock. Patients who appear restful and cheerful an hour after the insulin injection show the same changes as later when in deep coma with profuse sweating, or finally, up to within 15 minutes after the breaking off of the attack. Some cases, even in deep coma with a low blood sugar, show no electrocardiographic changes whatsoever. They gave their insulin intramuscularly whereas in earlier tests without exception the insulin had been given intravenously.

Possibly the absorption from the muscle tissue might lead to certain changes in the insulin which do not allow so direct an influence upon the heart muscle as if the insulin were given intravenously. They are confident it does not depend on the purity of the insulin because they obtained the changes when insulin first began to be manufactured and they were the same as at present when it is much purer.

Their practical conclusions were

- 1 That insulin does not exert on the healthy heart the anticipated harmful action which in general has been accepted, even with very low values of the blood sugar, a normal electrocardiogram could be obtained,

- 2 That their electrocardiographic studies show that even after months of induced severe hypoglycemic attacks permanent changes are not observable,

- 3 That all of their observations relate exclusively to patients with completely healthy heart muscle, and they cannot be considered as contradicting in any way results obtained in coronary disease after the administration of insulin.

In 50 per cent of Hadorn's cases, increase in the heart rate occurred and indeed often before the beginning of the hypoglycemia. In general, the view has been held that insulin is a parasympathetic stimulant. There is a difference of opinion on this score. A toxic dose of insulin acts through the central sympathetic chain to produce an out-pouring of adrenalin and so leads to a primary tachycardia. Even before hypoglycemia has occurred, a toxic insulin dose could, therefore, paralyze the vagus even though small doses of insulin might be stimulating. The tachycardias in Hadorn's group seemed to be due to adrenalin stimulation.

Smaller insulin doses may act as vagotropic drugs and may thus bring about the bradycardia which has frequently been observed. No increase in the work of the heart occurs when insulin slows the heart. Indeed, Bodo¹² as well as Visscher and Muller¹³ demonstrated with the Starling heart-lung preparation, that insulin had a tonic effect upon the heart, in-

creasing the power of the cardiac fibers without any increase in energy liberation

In cases where no change in pulse rate has occurred, we have positive and negative compensating chronotropic properties of insulin. That adrenalin is in some cases called forth by insulin is indicated by the fact that the systolic blood pressure rises while the diastolic blood pressure falls, a characteristic of adrenalin action. Secondly, leukopenia with a later increase in the leukocytes has occurred. One author holds that it is not the fall in the blood sugar which determined the symptoms of insulin shock but the strength of the opposing reaction from the adrenalin. Thus, the pounding of the heart, the tremor, and the pressure under the sternum are adrenalin symptoms whereas the hunger, weakness, sweating are the direct results of the hypoglycemia. The blood sugar level may fall to 40 milligrams after 5 units of insulin and yet no symptoms result whereas if it reached the same level with a dose of 40 units the symptoms may be marked. It is noteworthy that our children had practically no symptoms even with blood sugar values as low as 0.04 (40 milligrams) per cent.

A rise in blood pressure occurs only when the blood sugar falls below 60 milligrams, according to one author, but LaBarre and Houssa³ found that, in animals when the blood sugar fell under 95 milligrams the blood pressure rose due to the secretion of adrenalin.

Clinical Changes Unfavorable effects of insulin have been noted almost exclusively in hearts damaged by coronary disease. Thus, Schonbrunner⁴ described a 73 year old diabetic woman with a low Q_s , in whose electrocardiogram there developed regularly 15 minutes after insulin a negative inversion of the T-waves without simultaneous hypoglycemia. In 1923 at the New England Deaconess Hospital a man who had had angina pectoris for many years, died during the night 11 hours after receiving a dose of only 3 units of insulin. At autopsy, his heart had advanced coronary disease with old areas of infarction. At that time, when insulin was new, the possibility of its having precipitated this fatal attack required frank statement. Gigon,⁵ as well as others, has described diabetic patients with severe coronary disease who have died suddenly shortly after receiving insulin. As years have passed, the favorable effects of insulin have become more apparent. The following table shows that diabetics, with fatal coronary disease, live longer, the longer insulin was used.

TABLE II
Diabetics with Coronary Disease
The Advancing Age at Death During the Insulin Era

| | 1923-1926 | 1927-1929 | 1930-1932 | 1933-1935 |

| Number of Cases | 55 | 56 | 94 | 58 |

ANIMAL EXPERIMENTS

In animals negative T-waves have been noted in the electrocardiogram after a dose of insulin as well as changes in the heart rate and in the blood pressure. A direct toxic effect has been described affecting stimulus formation, stimulus conduction, and contractility of the heart muscle during a period of hypoglycemia due to insulin. It has been pointed out, however, that the variation in the T-waves and the level of the blood sugars are not parallel.

Rabbits, when given insulin and killed during hypoglycemia, showed about the same glycogen content as control animals. Both with intramuscular and intravenous injection of insulin they found T-wave depression in the animals. With very small doses of insulin (4 units) Hadorn¹ observed an increase in the height of the T-wave. In one case, however, the blood sugar fell to 21 milligrams without a T-wave change. In one animal, the blood sugar rose after 20 units of insulin and during this period they found an isoelectric T-wave. S-T depression did not occur in his animals. Lengthening of the Q-T interval occurred in the animals. With adrenalin injection into the animals, they show typical depressions of the T-wave, negative T-waves and often these were of the coronary type.

Milles and Smith⁶ injected epinephrine into the saphenous vein and the coronary artery and observed electrocardiographic changes. A reduction in the amplitude of the T-waves was found as well as other changes of the T-wave and actual inversion. Deviation of the S-T interval from the isoelectric line occurred as well as extrasystoles and actual ventricular fibrillation.

Douglas, Gelfand, and Shookhoff⁷ found that the injection of epinephrine into the muscles of the cat would produce marked displacement of the S-T segment in the electrocardiogram. These S-T changes were abolished by nitroglycerine, and were therefore attributed to coronary spasm. Milles and Smith⁶ attributed the changes caused by epinephrine to an increase of the myocardial requirements for oxygen beyond the available supply, with consequent functional anoxemia of the myocardium.

Soskin, Katz and Frisch⁸ produced hypoglycemia in animals in various ways and concluded that insulin exerts a specially harmful effect upon the heart regardless of hypoglycemia, a point of view difficult to understand when one remembers that insulin is a natural hormone produced physiologically throughout life.

In summary, the important thing is the question of the T-wave. The changes observed are of short duration, and may be reproduced by injection of adrenalin. Many factors such as anemia, CO poisoning, oxygen lack, general infections as well as digitalis itself cause temporary changes in the T-wave. At present, the balance of evidence indicates that the electrocardiographic changes following insulin injections are probably secondary adrenalin effects and without serious significance, except in the presence of coronary arteriosclerosis.

INSULIN AND CARDIAC METABOLISM

The effect of insulin upon the respiratory quotient, oxygen consumption in hyperglycemia and in hypoglycemia, glycogen deposit and changes in cardiac muscle during insulin action have been repeatedly studied and the results recently reviewed by Cruickshank⁹. In the isolated heart, in the presence of hyperglycemia, insulin increased the oxidation of sugar and the deposition of glucose as glycogen. When hypoglycemia of severe grade was produced, ordinarily the cardiac glycogen reserve is drawn upon. If the hypoglycemia persists, then the heart utilizes other sources of energy and can survive with no sugar in the blood. During the hypoglycemia the addition of insulin has a protective effect in that even then it causes the deposition of glycogen in the heart muscle.

Using diabetic dogs with experimental coronary occlusions, Himwich, Goldfarb and Nahum¹⁰ studied the cardiac metabolism and found data supporting the use of insulin and glucose. They studied 34 animals. They concluded that the infarcted area lost appreciable quantities of the glycogen which appeared in part as increased amounts of available carbohydrate and of lactic acid. Although the normal heart usually absorbs lactic acid from the blood, after occlusion the heart was found to pour lactic acid into the blood stream, probably due to the reduced oxygen supply to the infarcted area. Glucose was absorbed from the blood both before and after the coronary occlusion. These data again suggest that in diabetic patients, especially, the use of glucose and insulin may be of real value in cases with coronary occlusion. Furthermore, Himwich, Goldfarb and Fazikas¹¹ found that the heart muscle oxidizes non-fatty substances, that is, carbohydrates, very well.

Actually it must be remembered that the results of insulin hypoglycemia are chiefly dependent upon the degree to which sugar is lost from the blood and the length of time the tissues are without a supply of glucose from the blood. Certain tissues, like the liver, have a store of glucose upon which they can surely subsist. Other tissues, like the central nervous system, can withstand serious hypoglycemia for only a comparatively short time without the development of irreversible changes.

SUMMARY

1. Electrocardiograms in 25 young diabetics and the record of a fatal case of insulin hypoglycemia are reported.

2. Insulin hypoglycemia has no serious effect upon the normal diabetic heart. Bradycardia is as common as tachycardia.

3. Insulin hypoglycemia may, by reason of its accompanying stimulation of adrenalin secretion, have serious effects upon the heart damaged by coronary disease.

4. Insulin hypoglycemia of sufficient duration will cause irreversible changes in the central nervous system and death.

5 The proper use of insulin and diet in coronary disease complicating diabetes prolongs life

UNILATERAL HEMOGLOBINURIA ITS OCCURRENCE IN INFARCTION OF THE KIDNEY*

By EMANUEL LIBMAN, M D , F A C P , and ARTHUR M FISHBERG, M D ,
New York, N Y

HEMOGLOBINURIA is regarded as symptomatic of hemoglobinemia. A small amount of hemoglobin may be free in the blood plasma without appearing in the urine, being taken up and converted to bilirubin by the reticulo-endothelial cells. But the renal threshold for hemoglobin is apparently very low, so that hemoglobinuria is a fairly delicate indicator of hemoglobinemia. Contrary to hemoglobinuria, hematuria is practically always due to a local disorder of the kidneys or urinary passages, though in the so-called essential hematurias the anatomic substratum may be difficult to discover.

In the present note we desire to record briefly three observations showing that this distinction between the significance of hemoglobinuria and that of hematuria, while true in the vast majority of cases, does not invariably hold, occasionally, hemoglobinuria is due to a lesion of the kidney and is then unilateral if the renal affection is one-sided. A few instances of hemoglobinuria caused by renal disease are recorded in the literature. Thus, Bittorf¹ reports three cases of acute glomerulo-nephritis which, after apparently having been cleared up for months, underwent recurrences associated with hemoglobinuria. In each instance the hemoglobinuria appeared after exposure to cold. Since there was no evidence of hemolysis in the blood of an arm vein, the hemoglobin must have been freed in the kidney. He also states that he observed hemoglobinuria, in addition to hematuria, in a case of subacute bacterial endocarditis with embolic focal nephritis. Wagner² and Senator³ also mention hemoglobinuria in the course of acute or chronic Bright's disease. Our observations concern three instances of infarction of the kidney occurring in heart disease.

CASE REPORTS

Case 1 This patient was seen by one of us (E L) in consultation in 1919. She was a woman of 55 years who had suffered from mitral stenosis with auricular fibrillation for a number of years. She was suddenly seized with severe, cramp-like pain in the right side of the abdomen. Ovarian or appendicular disease was suspected. The urine at this time did not contain blood. Soon, however, the pain shifted to the left upper abdomen and the left kidney became palpable and tender. The leukocyte count was 32,000 with 82 per cent polymorphonuclears. The bladder urine was acid, contained albumin, a few erythrocytes, and some hyaline and granular casts. Roentgen-ray examination was negative for calculus. Cystoscopy was performed by

* Received for publication September 23, 1937

Dr Leo Buerger The urine from the right kidney was of normal color and contained albumin and casts and a few erythrocytes but not hemoglobin The urine from the left side was red and gave a positive guaiac reaction, but no erythrocytes were to be found in the sediment From the pelvis a large amount of old blood was evacuated The hemoglobinuria persisted for several days It then cleared up, as did the abdominal symptoms There was no recurrence of similar symptoms

Case 2 A woman of 30 years had had rheumatic heart disease since childhood She presented the classical signs of mitral stenosis On February 17, 1925 at 12 30 a m, when feeling comparatively well, she was suddenly seized with severe abdominal cramps, particularly in the right lower quadrant The pains lasted all night and were not relieved by repeated injections of codein Unfortunately the urine was not observed during the night

A specimen of urine obtained at 10 a m was acid and intensely red Very few erythrocytes were found in the sediment after centrifugalization, although numerous hyaline and granular casts were present The guaiac test was positive The protein content was 0.31 per cent

February 18, the urine was very red The sediment after centrifugalization contained very few erythrocytes, but numerous leukocytes and some hyaline and granular casts were present The protein content was the same as before The guaiac test was positive

February 19, the morning urine was still very red The guaiac test was positive The sediment after centrifugalization contained no erythrocytes but numerous granular casts

The evening urine was also very red and gave a positive guaiac reaction In the sediment only isolated erythrocytes were seen, and also a few casts and some polymorphonuclear leukocytes Some of the casts were stained golden by hemoglobin Large clumps of hemoglobin were present

Daily examination of the urine from February 20 to 23 revealed continuance of the hemoglobinuria in the absence of hematuria The hemoglobinuria disappeared on February 24 and did not return

During the first two days the right kidney (which was ptosed and readily palpable) was very tender, it was not notably enlarged The tenderness rapidly passed away, and the patient remained with only the symptoms of the preexisting heart failure It is of interest to note that one day after the infarction occurred, examination of the blood revealed 29,600 leukocytes per cubic millimeter, 94 per cent of which were polymorphonuclears

Case 3 A woman of 36 years was under observation because of orthopnea and swelling of the feet dating back to the last weeks of a pregnancy which had terminated five months earlier In a pregnancy 16 years before she had suffered from a pyelitis On admission to The Mount Sinai Hospital on February 18, 1936, the patient was cyanotic and orthopneic She had cardiac enlargement, tachycardia, and gallop rhythm There was engorgement of the lungs and liver and edema of the feet The blood pressure in the left arm was 170 systolic and 130 diastolic The pulsations in the right upper extremity were small and the oscillometric excursions diminished The urine was acid and contained a large amount of protein and scattered erythrocytes and leukocytes Although the urea nitrogen content of the blood was only 17 mg per cent, the concentration test revealed severe impairment of renal function, the maximum specific gravity was only 1.012 The roentgenogram revealed a calculus in the right kidney It was thought that the patient's symptoms were due to heart failure secondary to hypertension and perhaps coronary artery disease Whether the hypertension was essential in type or the result of a pyelonephritic contracted kidney was not clear

February 27, the patient was suddenly seized with severe knife-like pain in the left upper quadrant which persisted for about an hour The skin was cold and

clammy The pulse was feeble and rapid, the blood pressure unobtainable The urine was yellow in color In the sediment of the centrifuged urine, there were 100 to 200 leukocytes and 10 to 20 erythrocytes per high power field

February 28, she complained of left costovertebral pain radiating to the right upper quadrant There was shock tenderness in the left costovertebral region The temperature rose to 101° There was a leukocytosis of 21,000 with 76 per cent polymorphonuclears* Later in the day, the left kidney became palpable and tender The urine was unchanged in color There was no increase in the small number of erythrocytes found in the sediment of the centrifuged urine At this time, the nature of the attack was obscure, the most likely possibilities seemed to be left-sided renal colic of calculous origin (there was known to be a stone in the right kidney) or infarction of the left kidney

February 29, a specimen of urine was obtained which was burgundy red in color On centrifuging, there was a small amount of white sediment, but the supernatant fluid remained red and gave a very strongly positive guaiac reaction Spectroscopic examination of the supernatant fluid disclosed oxyhemoglobin in solution The sediment contained a moderate number of leukocytes, some of which were clumped, a few hyaline and granular casts, and about 20 erythrocytes per high power field On the basis of the hemoglobinuria, a diagnosis of infarction of the left kidney was made

From February 29 to March 2, inclusive, the burgundy red color of the urine due to the presence of dissolved hemoglobin persisted The sediment of the centrifuged urine contained between 1 and 6 erythrocytes per high power field The urine obtained on the morning of March 3, the day of death, was yellowish in color but still gave a strongly positive guaiac reaction

Necropsy revealed recent thrombosis of the right circumflex coronary artery and old occlusion of the left anterior descending branch of the left coronary artery There was myofibrosis of the anterior and posterior walls of the left ventricle with an aneurysm of the posterior wall Over areas of fresh myomalacia at the apices of the left and right ventricles were mural thrombi There was embolic occlusion of the left renal and superior mesenteric arteries The left renal artery, just beyond its origin, was occluded by a recent blood clot The left kidney was infarcted in toto, and was largely a dirty brown red in color The right kidney was the seat of pyelonephritic contraction

COMMENT

It is not immediately obvious why hemoglobinuria should occur in some instances of renal infarction while the large majority present hematuria The arteries of the kidney are typical end arteries in the sense of Cohnheim and renal infarcts are probably always anemic in their inception The gray-colored anemic area is usually surrounded by a red border of circulatory stasis and collateral hyperemia, with hemorrhages from dilated capillaries Microscopic examination of this portion shows the tubules filled with blood coming from the ectatic and ruptured intertubular capillaries This is the source of the *hematuria* which commonly occurs in infarcts Hemoglobinuria, however, when it occurs, is probably to be accounted for by a different mechanism Following the infarction, sufficient blood may reach the infarcted area to make it hemorrhagic In the autolysis which the infarcted area undergoes, large numbers of erythrocytes are destroyed with liberation of their hemoglobin Diffusion of the free blood pigment into neighboring

* High leukocytosis is not at all uncommon in infarction in any organ, it may also occur, as one of us⁴ has pointed out, in intracardiac thrombosis not followed by infarction

patent uriniferous tubules would cause hemoglobinuria. Evidence of such diffusion is found in hemosiderin deposits in the vicinity of old hemorrhagic infarcts. Because of the presence of old blood in the renal pelvis in the first case, the question must be brought up of the possibility of some hemolysis occurring there. It is to be noted that in Case 3, which came to postmortem examination, there was no old blood in the pelvis.

From the above observations, it is evident that hemoglobinuria is not absolutely pathognomonic of hemoglobinemia, for it occurs in connection with embolic infarction of the kidney. In our first case, the clinical picture was that of renal infarction and the hemoglobinuria was proved to be purely unilateral. In Cases 2 and 3 the clinical picture was the same as in Case 1. In Case 3 unilateral infarction was demonstrated at the postmortem examination. There is no reason to doubt that, although ureteral catheterization was not carried out in these two cases, the hemoglobinuria was also unilateral.

Judging by the third case, the phenomenon may well prove to be occasionally of practical diagnostic significance in the differentiation of infarction of the kidney from nephrolithiasis occurring in a patient suffering from cardiac disease. It is evident that studies should be made of separated specimens of urine, by means of ureteral catheterization, in cases of hemoglobinuria, particularly those in which the condition is not manifestly hemoglobinemic in origin.

THE PRESENT MORTALITY OF DIABETIC CHILDREN—A REMEDIABLE AND THEREFORE HOPEFUL INDEX OF THE FUTURE OF THE DIABETIC CHILD*

By ELLIOTT P JOSLIN, M D , F A C P , *Boston, Massachusetts*

WHEN a diabetic child dies today it causes me far more pain than half a generation ago. Before the discovery of insulin we did not expect diabetic children to live and if they did, we knew their existence would be much "labor and sorrow" as for people passing three score years and then until diabetic coma almost mercifully snatched them away. At that time diabetic children seldom survived a year, but in each quinquennium the duration of the fatal cases has nearly doubled, to 2.7 years for 1927, to 4.7 years for 1927-1932, to 9 years for 1932-1937. Today the situation is sharply altered. My own cases show a present mortality of about one per hundred per year, and calculations of the Metropolitan Life Insurance Company based upon the same group indicate that the life expectancy of the diabetic child of 10 years is 31.7 years. I know too that it is possible for a large part of these years to be spent happily and productively. Therefore, for diabetic children to die during the first or second decade of diabetes is truly deplorable.

Diabetic Coma. Until the use of insulin, diabetic coma came as a bolt from the night and took practically all children. But since we have had insulin you and I know that the death of a single child from diabetic coma signifies pure and unadulterated neglect and nothing else. Groping in the darkness we all were prior to insulin, we had reached the stage, nevertheless, that in hospitals coma had almost ceased to originate *suu genensis*. When insulin arrived we soon learned that even in actual coma it was the child with the best odds who had the best prognosis. In our series treated during coma at the New England Deaconess Hospital there has been 1 death in 83 children under 15 years of age and 3 deaths among 129 patients in coma between 15 and 20 years. At the Children's Hospital in Boston I am told by Dr. Butler that there has been no death in the institution from diabetes of any cause in the last 15 years. Contrast these facts with the report of the New York State Department of Health that in 1936 there were 107 deaths of the deaths of my diabetic patients with onset in childhood at the age of 15 years since I gave my first dose of insulin on August 7, 1911.

My diabetic children, and I use the word children in the fatherly sense, for once a child always a child to a parent, have numbered 1071 † before

* Received for publication August 12, 1937

† One hundred sixty-one children died before insulin was used in this clinic, August 1922

TABLE I

Fatal Results During 15 Years Treatment of 1063 Diabetic Children

August 1922-1937

The Causes of Death of 104 Diabetic Children

| Date | Deaths Coma | | Deaths Non-coma | | | | | | | | | |
|--|----------------|-------------|--------------------|-------------|-----------------|-------------|-------------------|-------------|----------------|-------------|------|-------------|
| | | | Tuber- culosis | | Infec- tions | | Hypo- glycemia | | Acci- dents | | Misc | |
| | No | Per Cent | No | Per Cent | No | Per Cent | No | Per Cent | No | Per Cent | No | Per Cent |
| 1922-1927 Total 35 Av Dur 2 7 yr | 32 | 91 | 0 | 0 | 3 | 9 | 0 | 0 | 0 | 0 | 0 | 0 |
| 1927-1932 Total 27 Av Dur 4 7 yr | 19 | 70 | 2 | 7 | 3 | 11 | 2 | 8 | 1 | 4 | 0 | 0 |
| 1932-1937 Total 42 Av Dur 9 yr | 18 | 43 | 7 | 17 | 11 | 26 | 2 | 5 | 1 | 2 | 3 | 7 |

August 7, 1922 and July 1, 1937 Of these, now scattered literally all over the world, there have come to my attention the deaths of one hundred and four It is possible there are a very few more, because the complete "follow-up" was over six months ago Among the causes of death diabetic coma is foremost and despite the relative innocuousness of this complication in childhood at the Children's Hospital and the Deaconess Hospital, just cited, in the first five-year period 1922-1927, 91 per cent of the 35 deaths were attributed to it In the second five years coma deaths fell to 70 per cent among the 27 deaths, and even in the five years ending now it has caused 43 per cent of the 42 fatalities This is actually higher than the coma mortality for all my patients of all ages in the eight years prior to insulin when it was only 41.6 per cent Yet you and I believe a death from diabetic coma to be needless and almost as inexcusable as a death from diphtheria

What can one do about it? We can reiterate the necessity for insulin both to doctor and patient in season and out of season, and of enough insulin whenever glycosuria exists, particularly in the presence of infections or complications of any sort and we can emphasize attention to the rules I have so often given patients

A Never omit insulin unless the urine is sugar free Keep to your diet and in case of an infection take more insulin if necessary to keep sugar free It is imperative to test the urine frequently during an acute illness

B If you feel sick and especially if you have FEVER, NAUSEA and VOMIT-

ING or even severe pains in the abdomen 1 Call a doctor 2 Go to bed 3 Take a cup of coffee, tea, cocoa shells or broth every hour and live upon acute illness diet (oranges 3, oatmeal, small portion, bread, 3 slices, milk, one quart, 1 egg, little butter) If the urine contains sugar, take regular insulin every hour under your doctor's direction 4 You need the entire time of a nurse or friend to care for you until you are well 5 Move the bowels with an enema

Should we teach a test for acetone or diacetic acid? So far I have hesitated to do so, first for fear the patient would assume too much responsibility and second, because it would simply add to the worries of the diabetic life Without it the coma mortality for all my patients similarly scattered was but 6.1 per cent for 981 deaths between January 1, 1930 and March 13, 1935

The patients themselves are fairly innocent of the charge of dying of coma I am sure you would agree if you read the accounts which I receive It would hardly do to print them because the laity would not realize that although the coma mortality for childhood cases is shockingly high, the rate of decrease is rapid and during the next five years probably the decline will go on and be accelerated And my reasons for this belief are that at present patients are taught more about their disease, doctors who are more conversant with insulin are in the saddle, and laboratory facilities, although often still deficient and in many localities unavailable at night and upon holidays and Sundays, are multiplying

Mobile coma units should be organized for areas without first class laboratories These might consist of (1) a technician with an outfit for analysis of urine, blood sugar, CO_2 combining power, non-protein nitrogen and sodium chloride, (2) a nurse and (3) a doctor The expense for furnishing such an outfit is relatively trifling compared with the cost of a neglected coma case in a hospital and it could operate throughout a radius of 100 miles It is unlikely that it would need to go many times to the same section, because the benefit which would accrue from it would be so obvious that the community would recognize and provide for the same

Each diabetic child must always be recognized as a coma possibility and thus the patient, the relatives and the family doctor should realize On this account, I believe there should be in advance a plan for hospital accommodations not only for coma but for all diabetic emergencies However, discretion must be exercised in giving instruction to patients upon medical subjects and this holds particularly for diabetic coma It is all right to picture the ease with which diabetic patients go into coma, but for very obvious reasons the disagreeable symptoms attending the process, as well as the discomforts of treatment should be stressed else in a moment of discouragement patients might deliberately welcome it as a means to an end

Pulmonary Tuberculosis Tuberculosis does not develop unannounced and it seems a shame that diabetic children who are so intimately in contact with the medical profession should acquire it, much less die of it In the first quinquennium following Banting's discovery we had no deaths from

tuberculosis and this applies as well to the entire group of children I saw prior to 1922 even as far back as 1898. The reason is plain—children did not live long enough in that period to acquire tuberculosis, or, if they did develop it, death from coma carried them off before tuberculosis became the lethal factor. Later between 1927 and 1932, when the average duration of diabetes for the 27 fatal cases in children had reached 4.7 years, tuberculosis caused two deaths (7 per cent) and in the next five years, 1932–1937, when the duration was nine years, there were seven cases (17 per cent) among the 42 deaths, making a total of nine fatalities from tuberculosis in the last 15 years. I might add that of my five fatal cases in children whose diabetic duration was 15 years or more, there was one death or 20 per cent from tuberculosis and, in fact, of the 10 deaths with a diabetic duration between 10 and 15 years there were four or 40 per cent from tuberculosis. From the above, it is plainly evident how essential it is to look for tuberculosis in diabetic children because it is almost as preventable and as needless as diabetic coma.

The ages, dates of onset of tuberculosis and of diabetes, and dates of deaths are given in table 2. Four of the children were males and five females. We have warned girls especially about tuberculosis because these five included two who had taken up nursing and the tuberculosis followed. Now we say no diabetic girl should become a nurse.

TABLE II
Nine Instances of Tuberculosis in 104 Deaths of Diabetic Children

| Case No | Sex | Birth Date | Onset | | | | Death | |
|---------|-----|--------------|--------------|------|--------------|------|----------------|------|
| | | | Diabetes | | Tuberculosis | | | |
| | | | Date | Age | Date | Age | Date | Age |
| 2274 | M | Jan 1915 | Jan 15, 1921 | 6 0 | Jan 1927 | 12 0 | Feb 13, 1934 | 19 1 |
| 3795 | F | May 2, 1910 | Dec 15, 1923 | 13 0 | Jan 1930 | 19 7 | Mar 17, 1930 | 19 8 |
| 3957 | M | Jan 22, 1912 | May 10, 1924 | 12 3 | Nov 1932 | 20 8 | Aug 10, 1933 | 21 6 |
| 4232 | F | Aug 21, 1907 | Sept 1921 | 14 1 | Mar 23, 1928 | 20 6 | Nov 25, 1936 | 29 3 |
| 4743 | F | June 9, 1908 | March, 1923 | 14 8 | Nov 1931 | 23 4 | May 25, 1936 | 27 9 |
| 5932 | M | June 4, 1913 | Feb 1927 | 13 7 | Jan 1932 | 18 6 | March 18, 1937 | 23 8 |
| 7041 | M | Jan 24, 1916 | April, 1922 | 6 3 | Feb 1930 | 14 1 | Oct 30, 1930 | 14 8 |
| 7047 | F | Jul 27, 1917 | June 5, 1928 | 10 9 | May, 1934 | 16 8 | Jan 1935 | 17 5 |
| 12385 | F | June 7, 1919 | Jan 1929 | 9 6 | Nov 1933 | 14 4 | Jan 9, 1934 | 14 6 |

The duration of the diabetes before the onset of the tuberculosis in no instance was less than 4.9 years and it did not exceed 8.6 years. The total duration of the diabetes varied between 5 years and 15.2 years and averaged 9.8 years which is actually greater by 2.4 years than for the 15 cases with onset in childhood dying from all causes in the first decade of life between January 1, 1930, and March 13, 1935, and 3.3 years greater than for the

29 cases with onset in childhood dying in the second decade of life in the same period

The duration of the tuberculosis from its onset until death varied between 0.1 of a year and 7.1 years. In five of the nine cases, it was less than one year. It is only fair to add, however, that we now have four living children with tuberculosis, and two with tubercle bacilli in the sputum. The tuberculosis has gone on in these living cases from 2.6 to 9.3 years.

The high incidence of tuberculosis in diabetic children was first called to my attention by my colleague, Howard F. Root, in 1934. At that time, he found it was 13 times as great in our diabetic group as in the comparable group of school children in Massachusetts. Therefore, we know how near the danger is. Incidentally, he also showed the extraordinary frequency of tuberculosis following recovery from diabetic coma in our own coma series. He found that within three years following recovery from coma, one in eight of our patients developed tuberculosis of the lungs. Since it happens that 10 per cent of our diabetic children at one time or another go through an attack of diabetic coma we have here a predisposing factor. But tuberculosis does not originate *de novo* and Dr. Root tells me that among these nine deaths from it in our children's series there was obvious exposure in four instances.

How shall this second group of needless deaths of diabetic children be averted? 1. Remembering the high incidence of tuberculosis in diabetic children much more energy should be expended both to prevent it and to detect it early. It is not a question of skill, but plain hard work and the use of well known methods. Tuberculin tests should be done yearly and if positive followed up by roentgen-rays. Moreover these rules should apply increasingly as long as the patients live. It costs us doctors nothing to secure a Wassermann test for our diabetic children and we never fail to take such, although as yet we have never had one positive. To secure a roentgenogram of the chest of a child, however, entails an expense which may reach \$15. The means for securing roentgen-rays should be simplified.

Infections Infections apart from tuberculosis have claimed 17 diabetic children and in a rising percentage for the three five-year periods from 9 to 11 to 26 per cent. Elsewhere when the follow-up of all our children for 1937 is complete, we shall report these in detail.

Hypoglycemia Hypoglycemia was responsible for four deaths. These cases already have been reported elsewhere. The first was soon after the discovery of insulin, far from Boston, and in an excellent hospital. The poor little child was wasted with a long standing infection, had undergone a multitude of therapeutic procedures, blood sugar tests were then made only with venous blood and what proved to be the crucial test, I understand, was postponed with the best intentions by a tender-hearted house officer until too late. The second death was in a child who sang in the choir Sunday night, had a convulsion the following morning at 2 a.m. and the

diagnosis being mistaken for diabetic coma received 200 units of insulin from a doctor who had never seen a case of coma or of an insulin reaction and at the moment was caring for a pregnant woman. Details about the other two are unsatisfactory and hypoglycemia was not demonstrated.

Miscellaneous In this group are included two deaths by trauma and one reported as cerebral hemorrhage. There are also two deaths during pregnancy.

Pregnancy occurs rather frequently among our girls who have outgrown childhood and although it can be successfully undergone there are real risks unless the greatest precautions for care during its course and at delivery are taken. Among our group of girls with onset of diabetes in childhood and now above the age of 18 years we know of at least 28 instances of pregnancy. We do know that in 26 the result was without harm to the mother, but there were two deaths—7 per cent—or fully 14 times the standard rates! Elsewhere these cases will be reported in detail by my colleague, Dr. Priscilla White.

CONCLUSIONS

When one contemplates the mortality of these children and realizes that 82 of them, 79 per cent, died needlessly—69 of coma, 9 of tuberculosis, 4 of hypoglycemia—and possibly that some of the others might have been saved with more alert and expert treatment during their infections or pregnancy, it is evident that the present mortality of diabetic children is a remediable and therefore a hopeful index of the future of the diabetic child.

August 7, 1937, begins the fourth quinquennium since my use of insulin and at its end I am confident a brighter report can be made than hitherto. It demands no new discovery, but only that same persistent, individual and educational effort for each child which Dr. Joseph H. Pratt displayed in the organization of his first tuberculosis class. That class suggested to me the educational methods which I have employed in the treatment of my diabetics and it is a satisfaction to record here my whole-hearted and appreciative recognition of his help.

EDITORIAL

POSTGRADUATE COURSES FOR MEMBERS OF THE COLLEGE

A fundamental purpose of the American College of Physicians is to raise the level of the practice of internal medicine. Important steps have been taken towards the attainment of this objective.

The development of the membership of the College to include a majority of the more outstanding clinicians, teachers and investigators of this country has in itself been important since it increases the prestige attached to membership in the College. Membership in the College thereby becomes a natural goal of the ambitious young internist. Since membership is to be won by furnishing evidence of careful study of teaching or research, of publications as well as of high ethical standards in practice, the more the College attracts young men the greater will be the influence of the College upon the future standards of internal medicine.

In its participation in the establishment and in the direction of the American Board of Internal Medicine the College has again demonstrated its belief that the title of internist should connote definite and serious study, training and experience. The requirements made of the applicant are not rigid but to meet them will require a training which is broader and more intensive than that usually afforded by the medical internship and residency. In many instances such training has been too exclusively a bedside apprenticeship to a few senior clinicians plus a large quota of time devoted to the routine details of administration of a medical service. No provision has been made for orderly study of the pathologic physiology of disease, nor for advanced training in the methods of clinical pathological research. With the exception of a relatively few institutions most hospitals give to their Residents a type of training which was developed half a century ago when all the hospital had to offer was concentrated clinical experience. It is certain that the establishment of the various Boards for the specialties is actively stimulating a revision of the whole residency system. These four years must be so reorganized as to give to the Resident more time for study, more systematic instruction, and a broader clinical experience than the average general hospital can furnish on its wards. Groupings of hospitals to furnish complete training, and alliances of hospitals with nearby medical schools offer possibilities worthy of consideration. A period of rotation in special consultant clinics (cardiology, nephrology, allergy, etc.) may also usefully supplement the ward and private patient experience of the Resident. It seems certain that in helping to establish the American Board of Internal Medicine the College has done a great deal to alter and improve the training of young internists.

These efforts of the College to raise the level of training for young physicians are, however, only a part of its educational program. From the

earliest days the best known activity of the College has been its Annual Session, and what is the significance of this week-long meeting if it is not a wholesome acknowledgment of the fact that the need for medical education does not stop when Fellowship in the College has been attained? Indeed the College is made up of a fellowship of students—life long students of the art of medicine,—and not by any means of a faculty of instructors. It is this eager interest on the part of the Fellows for the latest and the best in medical knowledge that adds so greatly to the stimulating atmosphere of our Annual Sessions. During that time we are all students together in a temporary school of our own creation.

This year will witness one of the most valuable of the Annual Sessions, since for the first time since very early days we are to meet in New York and to have laid before us the tremendous resources and activities of its great medical institutions. It seems certain that there will be a gathering of the membership of record breaking proportions.

This year witnesses also an innovation—the establishment by the College of a group of Postgraduate Courses for Fellows and Associates during the two weeks preceding the Annual Sessions which begin on the fourth of April. Each Fellow and Associate has already received the preliminary announcement from the Committee on Postgraduate Courses appointed by the Regents. The courses are offered at Harvard and Columbia Universities and at the University of Pennsylvania. In addition to general medicine there are to be special courses in the neuropsychiatric aspects of medicine, in metabolism, cardiovascular diseases and gastrointestinal diseases.

It is only through trial efforts of this type that the needs and the desires of the members of the College can be discovered. The establishment of such timely opportunities, which extend the postgraduate study period of the Annual Sessions, is to be looked on as a logical development of the essential program of the American College of Physicians.

REVIEWS

The Diagnosis and Treatment of Pulmonary Tuberculosis By JOHN B HAWES, M D, and MOSES J STONE, M D 215 pages, 14 X 21 cm Lea and Febiger, Philadelphia, Pa 1936 Price, \$2.75

This brief and concise textbook on pulmonary tuberculosis, in our opinion, fulfills a very definite and until now unsatisfied need in this field. It confines itself to the essentials of the disease and does not include theoretical discussions of the intricate and highly specialized subjects of immunity, resistance, allergy, etc. The student is referred in an excellent bibliography at the end of each chapter to more complete and larger works.

There are sections on the history of the disease, on history taking, on physical examination, on constitutional and local symptoms, on childhood tuberculosis, on the treatment of the disease and on tuberculosis in pregnancy and in industry.

The authors show great ability to compress the discussion of facts into small space without losing clearness or interest. Mature experience has enabled them throughout to justly distribute the emphasis so as to enable the reader to discern between the essential and the less important facts.

This excellent book should be in the hands of every practitioner of medicine and should be a standard of instruction for medical students. The manner of presentation, the data given and the bibliography make it worthy of the attention of all interested in tuberculosis.

Synopsis of Clinical Laboratory Methods By W E BRAY, B A, M D 324 pages, 12 X 19.5 cm C V Mosby, St Louis 1936 Price, \$3.75

An amazing amount of valuable information is contained in this small volume. Included are: A chapter listing the usual tests required by the various general and special hospital services, chapters on urinalysis (including diagnosis of pregnancy), on hematology, blood chemistry, gastric analysis, feces and intestinal parasites, puncture fluid examination and cerebrospinal fluid, sputum, bacteriology, water and milk examination, serology, basal metabolism, allergy tests, poisons and foreign substances, surgical pathology, and a chapter of formulae and a table of normal values.

Precautions to be observed in the collection of specimens and performance of tests are emphasized. A succinct statement of interpretation follows each method given.

In a book which is so modern in all other respects it is unfortunate that the author adheres to the older bacteriological nomenclature. There are very few errors of statement or typography. The choice of technics included seems judicious.

The summary treatment of topics makes the book more valuable as a guide to the trained technician or as a supplement to more detailed works on the subject than for use by the inexperienced as a single source. It is highly recommended as a reference.

J H M

Developmental Abnormalities of the Eye By IDA MANN, D Sc, M B, B S (London), F R C S (Eng) 444 pages, 16 X 24 cm Published for the British Journal of Ophthalmology by the Cambridge University Press 1937 Price, \$15.00

This book is divided into eleven chapters. The first three deal with general considerations as to how abnormalities of the eye develop as well as general abnor-

malities of both the skull and the eye. Chapters IV and V are in reference to abnormalities of the fundi, VI of the iris, VII of the iris and vitreous, VIII of the lens, IX of the cornea, X of the conjunctiva and sclera, and XI of the lids, lachrymal apparatus and the orbit.

In her consideration of the subject Miss Mann has not only described congenital abnormalities but also those abnormalities that develop later. Her previous study of the embryology of the eye combined with the clinical material as seen in her own and her colleagues' clinics makes the work doubly authoritative. There may be some disagreement with the author concerning the theories advanced as to the mechanism of some of the developmental defects but those proposed seem quite logical.

The first three chapters which deal with the production of developmental abnormalities as well as abnormalities of the head and the orbit, will be of interest to anatomists, neurologists and internists. The remaining chapters are of more especial interest to the ophthalmologists and will help to elucidate many an obscure finding.

The book is most excellent in its illustrations of which about 50 are completely or partially in color. The printing is clear and while a few errors of spelling and reference are noted, the book is to be highly recommended.

C A C

The Roentgenologist in Court By SAMUEL WRIGHT DONALDSON, A B, M D, F A C R. 230 pages, 15 X 24 cm. Charles C Thomas, Springfield 1937. Price, \$4.00.

This book is the result of much reading of the law in its relation to the practice of medicine, supported by extensive personal experience on the witness stand. It is a well written, concise and authentic work on a subject too often neglected by the busy physician. As its title implies, the book is supposed to concern itself primarily with the law in its relation to the roentgenologist, but the legal aspect of the practice of roentgenology differs very little from the practice of medicine in general, and consequently it contains very little that has not been said before. The chapters on "X-Ray Films and Evidence," "Ownership of Films" and "Conclusions" are of special interest to radiologists, but can be read with profit by every physician who is apt to be called upon to testify in cases where roentgen examinations have been made. Too much space has probably been given to the citation of selected cases and court decisions, that have but little bearing upon the medical witness. The increasing frequency of law suits and the blind faith that so many people place in the use of the x-rays, regardless of the qualifications and experience of the physician who made the examinations, bring the roentgenologist into court more frequently than many of his confreres. Any physician who is apt to be called as a witness will be sure to find his court experience less onerous after a careful perusal of this small volume. It is sure to find a welcome reception in the library of radiologists. It also contains much of value to members of the legal profession who are confronted in the court room with the presentation and interpretation of roentgen-ray films.

H J W

Vascular Disorders of the Limbs By SIR THOMAS LEWIS, C B E, F R S, M D, D Sc, LL D, F R C P, Physician in Charge of Department of Clinical Research, University College Hospital, London. 111 pages, 16 X 22.5 cm. The Macmillan Company, New York. 1936. Price, \$2.00.

This small volume can be highly recommended to practitioners and students. In it are found simple methods of testing circulation to the limbs and descriptions of disorders affecting the circulation of the limbs such as embolism and thrombosis, post-ischemic contractures, arteriosclerosis, thromboangitis obliterans, Ray-

naud's disease, acrocyanosis, erythrocyanosis and erythralgia. There are chapters dealing with the effects of circulatory arrest, arterial spasm, vasodilation and vascular disorders in diseases of the nervous system. The mechanisms and the treatment of these disturbances are described. Explanations of the maladies discussed are largely drawn from the author's researches published elsewhere. It should be noted that the author continues to attribute pain in circulatory arrest to the accumulation of products of muscular metabolism whereas evidence has been offered that this is not the sole factor. The book is remarkably condensed and at times this is annoying. One does not like to be referred to past or future discussions too frequently.

W S L, JR

Maternity and Post-Operative Exercises By MARGARET MORRIS, C S M M G 152 pages, 22 × 13.5 cm, Oxford University Press 1936 Price, \$2.00

The author is the founder of the International Institute of Margaret Morris Movement, and states that she has intended the book primarily for masseuses, midwives, and nurses who have taken the diploma of the Institute. However, surgeons, internists, and especially obstetricians may read this book with profit.

There are seven chapters of which five comprise the text material, and the last two describe the exercises in diagrams and words, and give exercise charts for specific indications. There is no index. The book is well printed in pleasing form.

The indications, precautions, effects, and anatomic and physiological reasons for the various exercises are carefully described. Individual exercises are described in words accompanied by clear and easily understandable original outline drawings by the author. The basic importance of proper breathing during the performance of the exercises is stressed. All the exercises are gently progressive. A special group of corrective exercises is outlined.

It is hoped that the members of the medical profession will be interested in this book, since the author stresses that the exercises should be carried out under medical supervision.

COLLEGE NEWS NOTES

GIFTS TO THE COLLEGE LIBRARY

Grateful acknowledgment is made of the receipt of the following donations to the College Library of publications by members

Books

- Dr Jacob C Geiger (Fellow) and Paul J Hanzlik (Fellow), San Francisco, Calif —“ A Handbook of Accepted Remedies Symptoms and Treatment of Poisoning, Diagnostic Procedures, Miscellaneous Information ”,
Dr Raphael Isaacs (Fellow), Ann Arbor, Mich, and Dr Hiram B Weiss (Fellow), Cincinnati, Ohio—“Manual of Clinical and Laboratory Technic ”,
Dr Frederick R Taylor (Fellow), High Point, N C—reprints of Chapters XII-A on “ Albinism,” XL-A on “ Arachnidism The Clinical Effects of Spider Bite ” and XLIII-A on “ Unusual Diseases and Symptom-Complexes not Discussed in Other Chapters (continued) ” from the Oxford Loose Leaf Medicine

Reprints

- Dr Norbert Enzer (Fellow), Milwaukee, Wis —1 reprint
Dr William W Graves (Fellow), St Louis, Mo —12 reprints
Dr Paul J Hanzlik (Fellow), San Francisco, Calif —4 reprints
Dr Elwood A Sharp (Fellow), Detroit, Mich —5 reprints
Dr Barnett Greenhouse (Associate), New Haven, Conn —1 reprint
Dr Florimond LeBlanc (Associate), Elgin, Ill —1 reprint
Dr Robert P Wallace (Associate), New York, N Y —1 reprint
Dr John O Woods (Associate), New Castle, Pa —1 reprint

Dr E J G Beardsley (Fellow and Governor for Eastern Pennsylvania for the College) Philadelphia, was the guest of the Westmoreland County Medical Society at Greensburg (Pa), on November 9 A clinic of patients exhibiting various cardiovascular disorders was held in the Westmoreland Hospital

Dr Beardsley also addressed the members of the Atlantic County (N J) Medical Society, Atlantic City, November 12, on “ The Man of Fifty ”

Dr William R Brooksher (Fellow), Fort Smith, has been appointed a member of the advisory council of the maternal and child health division of the Arkansas State Board of Health

The twelfth annual series of Friday Afternoon Lectures of the New York Academy of Medicine began November 19 The following Fellows of the College were scheduled to give lectures

November 19, Dr Robert L Levy, New York, “ Drugs in the Treatment of Heart Disease ”,

December 17, Dr Eugene M Landis, Philadelphia, “ Recent Advances in the Diagnosis and Treatment of Peripheral Vascular Diseases ”

Dr Lewis B McBrayer (Fellow), Southern Pines, N C, has retired as managing director of the North Carolina Tuberculosis Association, which position he has held since 1915, when the association was founded. Dr McBrayer also resigned as secretary of the Medical Society of the State of North Carolina

Dr David I Abramson (Associate), Brooklyn, has been appointed director of the department of cardiovascular research at the Jewish Hospital, Cincinnati

Dr Alex F Robertson, Jr (Fellow), Staunton, was elected president-elect of the Medical Society of Virginia at the annual meeting at Roanoke, October 12-14

Dr A Comingo Griffith (Fellow and Governor for Missouri), Kansas City, was recently elected president of the Jefferson D Griffith Chapter of the Association of Military Surgeons

Dr Elmer L Sevringhaus (Fellow), Madison, Wis, and Dr Arlie R Barnes (Fellow), Rochester, Minn, were guest speakers at the annual meeting and clinical conference of the Southwestern Medical Association, held at Phoenix, Ariz, November 18-20

Dr J Arthur Myers (Fellow), Minneapolis, addressed the annual public meeting and "health crusade" of the District of Columbia Tuberculosis Association, November 22, on "Modern Methods in the Control of Tuberculosis"

Dr Elliott P Joslin (Fellow), Boston, was a guest speaker on the dedicatory program of the new building of the Evangelical Deaconess Hospital, Detroit, November 10

Dr Arthur M Master (Fellow), New York, delivered the third of a series of lectures on heart disease, sponsored by the New York Heart Association, December 14, on "Use of Electrocardiograms in the Diagnosis and Prognosis of Coronary Thrombosis"

Dr S Spafford Ackerly (Fellow), Louisville, was elected vice president of the recently organized Kentucky Psychiatric Association at a meeting in Lexington

The Northeastern Indiana Academy of Medicine was addressed at Kendallville, October 28, by Dr Arthur E Mahle (Fellow), Chicago, on "Recent Advances in Medical Management of Peptic Ulcer"

At a meeting of the Hennepin County Medical Society, Minneapolis, November 10, Dr Carl V Weller (Fellow), Ann Arbor, spoke on "Intrinsic Factors in the Causation of Cancer"

Dr J Arthur Myers (Fellow), Minneapolis, president of the National Tuberculosis Association, was the guest speaker at the annual meeting of the New Jersey Tuberculosis League in New Brunswick, October 22

At the annual dinner of the Association for the Advancement of Industrial Medicine and Surgery, held October 20, Dr Albert E Russell (Fellow), U S Public Health Service, spoke on "Syphilis Control in Industry"

Dr B B Vincent Lyon (Fellow), Philadelphia, was a guest speaker at the sixth annual graduate program of the Summit County (Ohio) Medical Society Dr Lyon spoke on "Methods of Diagnosis and Treatment of Cholecystitis" and "Diagnosis and Management of Peptic Ulcer"

Dr Samuel B Scholz, Jr (Fellow), Philadelphia, was elected president of the Association of Life Insurance Medical Directors at the annual meeting in New York City recently

At its meeting in San Francisco in October, the Association of American Medical Colleges elected Dr Willard C Rappleye (Fellow), Dean of the College of Physicians and Surgeons of Columbia University, New York, as its president-elect, while Dr William S Middleton (Fellow), Madison, Wis, was elected vice president

The thirty-third annual meeting of the American Society of Tropical Medicine was held in New Orleans, November 30-December 3, in conjunction with the Southern Medical Association Dr George W McCoy (Fellow) of the U S Public Health Service delivered the second Charles Franklin Craig Lecture on "The History of Leprosy in the United States" Another guest speaker at the sessions was Dr William M James (Fellow and Governor for Panama and the Canal Zone for the College), Panama, R P, who spoke on "Emetine Therapy"

Dr Priscilla White (Fellow), Boston, was a guest speaker at the Fifth Annual Scientific Meeting of the Georgia Pediatric Society, December 9 Dr White spoke on "Endocrine Problems in Juvenile Diabetes" and "Recent Problems in Juvenile Diabetes"

Memorial rooms for the late Dr Henry R M Landis (Fellow), Philadelphia, for many years director of the clinical and sociological departments of the Henry Phipps Institute, University of Pennsylvania, have been established in the suite he occupied at the Institute

The following Fellows of the College were guest speakers on the program of the Southern Medical Association's annual meeting at New Orleans, November 30-December 3

Dr Stewart R Roberts, Atlanta, Ga , "Your Health and Mine",
Dr Robert A Cooke, New York, "Medical Problems of the Allergist",
Dr Priscilla White, Boston, "Protamine Insulin in the Treatment of Juvenile Diabetes",
Dr Walter C Alvarez, Rochester, Minn , "Some Stages in the Development of Gastro-Enterology",
Dr Lawrence Reynolds, Detroit, "Pulmonary Cysts",
Dr William D Cutter, Chicago, "The Appraisal of Medical Schools"

Dr Henry I Klopp (Fellow), Allentown, Pa , has been superintendent of the Allentown State Hospital since its founding. On October 12 the twenty-fifth anniversary of the opening of the hospital was celebrated with a special program. Dr James Allen Jackson (Fellow), Danville, Pa , presented a paper on "Extra-Institutional Clinical Activities in Twenty-Five Years". An oil painting of Dr Klopp was unveiled as the gift of the medical societies of Lehigh, Northampton and Bucks counties and the Lehigh Valley Homeopathic Society.

Dr William Gerry Morgan (Fellow), Washington, D C , was the chief guest speaker at the annual staff banquet of the Reading (Pa) Hospital on November 3, 1937. Dr Morgan was a resident intern at the old Reading Hospital in 1893. Memorials to two physicians, Dr Charles H Hunter, one of the founders of the hospital, and Dr Charles G Loose, for fifty-three years a member of the staff, and to Mr Gustav R Oberlaender, for many years President of the Board of Directors, were unveiled.

Solomon Strouse (Fellow) has recently received the following appointments: Associate Clinical Professor of Medicine at the University of Southern California, Attending Physician at the Los Angeles County General Hospital, Visiting Physician at the Cedars of Lebanon Hospital, Los Angeles, California.

Dr William C Voorsanger (Fellow), San Francisco, has been elected president of the San Francisco County Medical Society for the year 1938.

Dr David Riesman, Professor of the History of Medicine in the University of Pennsylvania, and Professor of Clinical Medicine in the Graduate School of the University, delivered the Vanuxem lectures at Princeton University on December 7, 8, 9 and 10. The lectures were on the general topic "Medicine in Contemporary Culture," the first being on "Medicine—Art and Science", the second, on "Superstitions, Cults and Medical Ethics", the third, on "The Family Doctor, Past and Future" and "Medicine as a Career", the fourth, on "The Social Outlook in Medicine".

Dr Carl J Wiggers (Fellow), Professor of Physiology, Western Reserve University, School of Medicine, has recently returned from the Orient, where he delivered a series of 16 lectures in Canton, Hong Kong, Shanghai, Peiping, Seoul, Kyoto and Tokyo. Professor Wiggers has accepted an invitation to address the Sixth National Congress of Medicine in Cordoba, Argentine, in October 1938, the other

guest speakers being Professor Gregorio Marañon from Madrid and Professor Volhard from Germany

The Annual Meeting of the Illinois Members of the American College of Physicians outside of Chicago was held at Bloomington, Illinois, on October 14, 1937, under the chairmanship of Dr Samuel E Munson, Governor Dr Edgar M Stephenson and Dr Gerald M Cline served as a Committee on Arrangements The meeting began at 3 o'clock in the afternoon and an interesting medical program was presented

"Arterio-Sclerotic Heart Disease," Dr Nathan S Davis, III, Chicago, Ill, Assistant Professor of Medicine, Northwestern University Medical School

"Current Endocrine Problems in Gynecology," Dr Elmer R Sevringhaus, Madison, Wisconsin, Associate Professor of Medicine, University of Wisconsin Medical School

"Peripheral Circulatory Failure," Dr Louis M Warfield, Milwaukee, Wisconsin, Former Professor of Clinical Medicine, Marquette University, Former Professor and Head of the Department of Medicine, University of Michigan

"The American Board of Internal Medicine, and Other Important Medical Questions," Dr Walter L Bierring, Des Moines, Iowa, Chairman, American Board of Internal Medicine, Past-President, American Medical Association

Dr Munson, as Chairman, reviewed for the Fellows of the College present the events of the last year in the history of the College and rendered a tribute to Dr Frank Smithies whose death has occurred since the preceding Annual Regional Meeting, at which he had been present as a guest and speaker

The afternoon program was followed by dinner at 6 30 and adjournment at 10 00 o'clock The meeting was excellently attended by Fellows of the College from Illinois

ABSTRACT OF MINUTES OF THE BOARD OF REGENTS

PHILADELPHIA, PA

December 12, 1937

A regular meeting of the Board of Regents of the American College of Physicians was held December 12, 1937, at the College Headquarters, Philadelphia, Pa, the meeting being called to order at 10 20 a m by President James H Means, with the following present

James H Means, President
William J Kerr, President-Elect
David P Barr, First Vice President
William D Stroud, Treasurer
George Morris Piersol, Secretary-General
James B Herrick
Robert A Cooke
Jonathan C Meakins
Hugh J Morgan
James E Paulin
James D Bruce
Egerton L Crispin
James Alex Miller
Francis M Pottenger
Walter L Bierring
Ernest B Bradley
Roger I Lee
Sydney R Miller
Walter W Palmer
O H Perry Pepper
Maurice C Pincoffs
Charles H Cocke

and with the Executive Secretary, Mr E R Loveland, acting as secretary of the meeting

On motion by Dr Paulin, seconded by Dr Bierring and unanimously carried, the reading of the Minutes of the St Louis Meeting was dispensed with

Mr E R Loveland, Executive Secretary, read communications from Dr G Gill Richards and Dr William Gerry Morgan, the only absentees at the meeting

The secretary also read several communications from public officials, physicians and one in particular from Dr Willard C Stoner, renewing the invitation from the City of Cleveland for the College to convene there in 1939

The Executive Secretary further read a set of communications from public officials, the Academy of Medicine and, in particular, from Dr Julien E Benjamin, presenting an official invitation for the College to convene in Cincinnati in 1939 Mr Loveland reminded the Board that invitations are still outstanding from New Orleans, San Francisco, St Paul and Washington for 1939

Dr Ernest B Bradley spoke in favor of the Cincinnati invitation, and expressed the opinion that Cincinnati's facilities and accommodations would be adequate for the College

On motion by Dr James E Paulin, seconded by Dr Sydney R Miller and regularly carried, it was

Resolved, that the Executive Secretary be instructed to visit, in advance of the New York Session in April, any of the cities from which invitations have been received, in order to inspect their facilities and accommodations

The Secretary brought to the attention of the Board that Dr Clement R Jones, of Pittsburgh, had presented a copy of the first edition and Dr C W Waddell, of Fairmont, W Va, had presented copies of both the first and second editions of the ANNALS OF MEDICINE, Volume I, 1920, to be added to the College archives. These were the first issues of the first journal sponsored by the American College of Physicians and the American Congress on Internal Medicine, but during the intervening years of changes in administration, all official copies of these issues had disappeared. The copies presented were in good state of preservation, and are a valuable addition to the College records.

On motion by Dr Roger I Lee, seconded by Dr James E Paullin, and regularly carried, it was

Resolved, that a vote of thanks be extended to the donors, Dr Clement R Jones and Dr C W Waddell.

Dr David P Barr, Chairman of the Committee on Fellowships and Awards, read communications by Dr George W Pickering, of London, and Dr Myron Prinzmetal, the 1936-37 Research Fellow, describing the work of Dr Prinzmetal during the year—Dr Pickering commending the College for awarding the Fellowship to Dr Prinzmetal, and Dr Prinzmetal expressing his deep appreciation to the College.

The following resolutions were unanimously adopted concerning the transfer of securities by the Treasurer some months previous.

Resolved, that the Treasurer of the American College of Physicians be and is authorized and directed, in accordance with the recommendations of the Finance Committee, to sell, assign and transfer fifty (50) shares General Motors common stock, Certificate No C643-886, in the name of this corporation.

Resolved, that the Treasurer of the American College of Physicians be and is authorized and directed, in accordance with the recommendations of the Finance Committee, to sell, assign and transfer forty-five (45) shares Mid-Continent Petroleum Company stock, Certificate No 7815, in the name of this corporation.

Pending the arrival of Dr George Morris Piersol, Secretary-General, President Means reported the following deaths of members since the preceding meeting of the Board of Regents as follows.

Fellows

| | | |
|-------------------------|---------------------|--------------------|
| Avery, Jacob Fowler | La Jolla, Calif | June 25, 1937 |
| Behlow, William Wallace | Palo Alto, Calif | April 29, 1937 |
| Betts, Arthur | Spokane, Wash | October 17, 1937 |
| Breed, Lorena M | Pasadena, Calif | October 20, 1937 |
| Brown, Douglas | Castle Point, N Y | June 6, 1937 |
| Chester, John Leonard | Detroit, Mich | May 31, 1937 |
| Crane, Augustus Warren | Kalamazoo, Mich | February 20, 1937 |
| Daland, Judson | Philadelphia, Pa | August 14, 1937 |
| Daley, Daniel Francis | Kingston, Pa | April 24, 1937 |
| Dalton, Eugene S | Brooklyn, N Y | April 19, 1937 |
| Dickie, Jamie W | Southern Pines, N C | July 6, 1937 |
| Eggleston, Elmer L | Battle Creek, Mich | July 7, 1937 |
| Elrod, John Oscar | Forsyth, Ga | April 21, 1937 |
| Ferris, Albert Warren | East Orange, N J | October 4, 1937 |
| Grewe, John Ernest | Cincinnati, Ohio | October 29, 1937 |
| Hardin, Ronda Horton | Banner Elk, N C | October 9, 1937 |
| Howard, Leroy Taylor | M C, U S Army | September 30, 1937 |

| | | |
|--------------------------|--------------------|--------------------|
| Landis, Henry R M | Philadelphia, Pa | September 14, 1937 |
| Lemann, Isaac Ivan | New Orleans, La | September 2, 1937 |
| Lyter, J Curtis | St Louis, Mo | October 9, 1937 |
| Mason, Elijah Lumbia | Washington, D C | August 30, 1937 |
| McCampbell, Eugene F | Columbus, Ohio | May 8, 1937 |
| Miller, Joseph Leggett | Chicago, Ill | August 6, 1937 |
| Myers, Harold Bunce | Portland, Ore | March 6, 1937 |
| Oleson, Richard B | Lombard, Ill | August 6, 1937 |
| Pothuisje, Peter Jurgens | Denver, Colo | June 4, 1937 |
| Samenfeld, Joseph | Brooklyn, N Y | September 5, 1937 |
| Sherrill, Coite Long | Statesville, N C | June 24, 1937 |

| Surnamer, Isaac | Paterson, N J | April 23, 1937 |
| Sweet, Earl | Los Angeles, Calif | May 22, 1937 |
| Walcott, Harry Gilmer | Dallas, Tex | June 2, 1937 |
| Waples, Frank Alsworth | Houston, Tex | March 4, 1937 |
| Warr, Otis Sumter | Memphis, Tenn | March 22, 1937 |
| Wyckoff, John | New York, N Y | June 1, 1937 |

Associates

| | | |
|-------------------------|----------------|-------------------|
| Calhoun, Abner Wellborn | Atlanta, Ga | November 3, 1937 |
| Sprenkel, Vaughan LeRoy | Allentown, Pa | June 18, 1937 |
| Walker, Thomas Tipton | Watertown, N Y | November 13, 1937 |

President Means also, on behalf of the Secretary-General, reported the following additions to the Life Membership Roster since the last Regents' meeting

Estella G Norman, Miami Springs, Fla
 Charles W Waddell, Fairmont, W Va
 Hugh Francis Crawford, Memphis, Tenn
 Louise Taylor-Jones, McLean, Va

These additions make a total of 83 Life Members, 4 of whom are now deceased, leaving a remainder of 79

Dr James E Paullin, Chairman of the Committee on Public Relations, reported as follows

(1) Resignations of the following be accepted

Colonel William Denton (Fellow), M C, U S Army
 Dr D Grant Campbell (Associate), Montreal, Que, Canada
 Dr George H Jantzen (Associate), Queens Village, N Y
 Dr Frederick H Lamb (Associate), Davenport, Iowa
 Dr Maurice T Root (Associate), West Hartford, Conn
 Dr Francis C Weber (Associate), Newark, N J
 Dr James H Wheeler (Associate), Henderson, N C

(2) That the request of Dr George H Spivey (Fellow), Hot Springs, S D, to be dropped from the Roster be acceded to

On motion by Dr James E Paullin, seconded by Dr Jonathan C Meakins, and unanimously carried, it was

Resolved, that the Board of Regents approve in full the recommendations of the Committee on Public Relations embodied in the three sections above

Dr Paullin, for the Committee on Public Relations, then reported that a "communication from Dr Russell M Wilder, of the Mayo Clinic, including a letter to Dr James H Means, President of the American College of Physicians, concerning

newspaper publicity in the *Chicago Daily Times*, has been received and read Your Committee is in sympathy with the predicament in which the Mayo Clinic finds itself and with the embarrassing position in which they are placed, but it knows of no remedy which can be utilized to overcome such publicity"

On motion by Dr Paullin, seconded by Dr Jonathan C Meakins and unanimously carried, it was

Resolved, that the Board of Regents approve of this part of the report of the Committee on Public Relations

Dr Paullin proceeded with his report "A communication from Dr Noiman Strauss, of New York City, in which he propounds two questions and asks for an expression of opinion by the Board of Regents concerning a division of fees, has been received It is the advice of the American College of Physicians that in professional dealings with patients, these be conducted openly and frankly, and that the principles of the medical ethics of the American Medical Association be followed, and that there shall be no fee-splitting and no attempt whatsoever made either at evasion or circumvention of these principles Bills for medical services presented by various practitioners should be rendered separately, in order that no suspicion of motive be aroused A copy of this reply to Dr Strauss should be sent to Dr Olin West, Secretary of the American Medical Association, Chicago, and to Dr George E Follansbee, Chairman of the Judicial Council of the American Medical Association, 629 Euclid Ave, Cleveland, Ohio, together with a copy of the Pledge, which each member of the American College of Physicians takes on induction into Fellowship"

On the suggestion of Dr James Alex Miller, the recommendation of the Committee was amended, providing for the insertion of the following "Consequently, both questions submitted by Dr Strauss are in violation of these principles"

On motion by Dr Paullin, seconded by Dr James Alex Miller and unanimously carried, it was

Resolved, that the Board of Regents approve of the above section of the report of the Committee on Public Relations

Dr Paullin continued the report of his Committee "A communication from Dr Paul D Abramson, Secretary of the Shreveport Medical Society (Shreveport, La), was received and read It is the opinion of your Committee that the American College of Physicians has no suggestion to make concerning this resolution (regarding an Act of their State Legislature constituting a State Hospital Board and opening charity state hospitals), and we respectfully refer the Shreveport Medical Society to the American Medical Association, who would properly have jurisdiction over such matters"

On motion by Dr Paullin, seconded by Dr F M Pottenger, and unanimously carried, it was

Resolved, that the Board of Regents approve of the above section of the report of the Committee on Public Relations

Dr Paullin proceeded with his report "Your Committee is in receipt of a set of resolutions from the Committee of Physicians, of which Dr John P Peters, of New Haven, Conn, is the secretary, in which certain principles and proposals are outlined, and which have been signed by 430 physicians of the United States We are also in receipt of another set of principles submitted by Dr Eugene S Kilgore, of San Francisco In addition, there is a letter from Dr Henry M Thomas, Jr, Governor of the College for Maryland Your Committee feels that these resolutions and proposals should be brought to the attention of the Board of Regents as a whole, without any recommendation of the Committee on Public Relations"

On motion by Dr Paullin, seconded by Dr Charles H Cocke, and unanimously carried, it was

Resolved, that these proposals and recommendations be received and filed with the secretary

Dr David P Barr, Chairman of the Committee on the ANNALS OF INTERNAL MEDICINE, reported that the Committee is profoundly satisfied with the progress of the ANNALS, and while it is quite possible that various extensions of activity could be made, the work that the ANNALS is now doing seems to the Committee very good indeed, and, therefore, no specific recommendations were brought before the Board. However, he expressed the opinion that sooner or later the Editor would need additional help, particularly if new departments in the ANNALS are to be established. One of the matters discussed by the Committee was that of a department for postgraduate education, a service to internists and physicians throughout the country, which would keep them informed of postgraduate courses available here and abroad. There had also been some discussion of extension of monographs or special articles, similar to the one on rheumatism, which appeared several years in the ANNALS. The Committee in conclusion reported that in spite of a materially increased size of the ANNALS during the past year and, consequently, increased expenses, the ANNALS still is splendidly solvent.

On motion by Dr George Morris Piersol, seconded by Dr William D Stroud, and unanimously carried, it was

Resolved, that the report of the Committee on the ANNALS OF INTERNAL MEDICINE be adopted

Dr Sydney R Miller, Chairman of the Committee on Credentials, presented his report. "The Committee has considered 95 candidates for Fellowship and 183 candidates for Associateship. An analysis of the recommendations of the Committee concerning candidates for Fellowship is as follows:

| | |
|-------|---|
| 47 | to be advanced from Associateship |
| 19 | direct elections |
| 14 | to be advanced from Associateship 'as of April 3, 1938' |
| 2 | recommended for Associateship |
| 8 | deferred |
| 5 | rejected |
| <hr/> | |
| 95 | |

"An analysis of the action recommended by the Committee in connection with the candidates for Associateship is as follows:

| | |
|-------|-------------------------------------|
| 146 | elected Associates |
| 2 | elected Fellows |
| 7 | deferred for additional credentials |
| 28 | rejected |
| <hr/> | |
| 183 | |

Typed lists of all candidates were distributed for use by each member of the Board of Regents."

On motion by Dr Sydney R Miller, seconded by Dr James E Paullin, and unanimously carried, it was

Resolved, that the following list of 68 be and herewith are elected to Fellowship in the American College of Physicians as of this date, December 12, 1937
